The entanglement assisted independence number is a graph theoretic quantity introduced in the context of zero-error channel capacity, and is equal to the number of codewords that can be transmitted error-free through a classical channel with the help of entanglement. Beigi introduced a quantity β as an upper bound on the entanglement assisted independence number. We adapt and extend Beigi's argument to the context of source-channel coding (communication in the presence of side information). Entanglement assisted source-channel coding is possible only if there exists a set of vectors satisfying certain orthogonality conditions related to suitably defined graphs G and H . We show that such vectors exist if and only if $\vartheta(\overline{G}) \leq \vartheta(H)$ where ϑ represents the Lovász number. We also obtain similar results for the related Schrijver ϑ^- and Szegedy ϑ^+ numbers.

These inequalities reproduce or generalize several known results, provide a bound on entanglement assisted source-channel coding, and provide tightened bounds on entanglement assisted one-shot zero-error capacity. In particular, we show that the entanglement assisted independence number is bounded by the Schrijver number: $\alpha^*(G) \leq \vartheta^-(G)$. Therefore, we are able to disprove the conjecture that the one-shot entanglement-assisted zero-error capacity is equal to the integer part of the Lovász number. Finally, Beigi posed the question of whether $\beta(G) = \lfloor \vartheta(G) \rfloor$. We answer this in the affirmative and show that a related quantity is equal to $\lceil \vartheta(G) \rceil$. We show that a quantity $\chi_{\text{vect}}(G)$ recently introduced in the context of Tsirelson's conjecture is equal to $\lceil \vartheta^+(\overline{G}) \rceil$.

I. INTRODUCTION

The source-channel coding problem is as follows: Alice and Bob can communicate only through a noisy channel. Alice wishes to send a message to Bob, and Bob already has some side information regarding Alice's message. Alice encodes her message and sends a transmission through the channel. Given the (noisy) channel output along with his side information, Bob must be able to deduce Alice's message with zero probability of error (we always require zero error throughout this entire paper). An (m, n) -coding scheme consists of encoding and decoding operations which allow sending m messages via n uses of the noisy channel. The *cost rate* η is the infimum of n/m over all (m, n) -coding schemes.

There are two special cases which are particularly noteworthy. If the messages are bits and there is no side information then the inverse of the cost rate, $1/\eta$, is the *Shannon capacity* [1], the number of zero-error bits that can be transmitted per channel use in the limit of many uses of the channel. On the other hand, communication over a perfect channel with side information was considered by Witsenhausen [2]; the corresponding cost rate is known as the *Witsenhausen rate*. The general problem, with both side information and a noisy channel, was considered by Nayak, Tuncel, and Rose [3].

The Shannon capacity of a channel is very difficult to compute, and is not even known to be decidable. However, a useful upper bound on Shannon capacity is provided by the ϑ number introduced by Lovász [4]. The Lovász ϑ number also provides a lower bound on the Witsenhausen rate [3] and, in general, the cost rate.

Recently it has been of interest to study a version of this problem in which the parties may make use of an entangled quantum state, which can in certain cases increase the zero-error capacity of a classical channel [5, 6]. The Lovász ϑ number upper bounds entanglement assisted Shannon capacity, just as it does classical Shannon capacity [7–9]. Beigi’s proof [7] proceeds through a relaxation of the channel coding problem, with the relaxed constraints consisting of various orthogonality conditions imposed upon a set of vectors. We find that a Beigi-style relaxation of source-channel coding leads to a set of constraints that are exactly characterized by monotonicity of ϑ . This has a number of consequences. Beigi defined a function β as an upper bound on entanglement assisted independence number and posed the question of whether β is equal to $\lfloor \vartheta \rfloor$. We answer this in the affirmative and show that a similarly defined quantity is equal to $\lceil \vartheta \rceil$. We show that ϑ provides a bound for the source-channel coding problem. As a special case this reproduces both Beigi’s result as well as that of Briët et al. [10] in which it is shown that ϑ is a lower bound on the entanglement assisted Witsenhausen rate.

A slightly different relaxation of source-channel coding leads to three necessary conditions for the existence of a $(1, 1)$ -coding scheme in terms of ϑ and two variants: Schrijver’s ϑ^- and Szegedy’s ϑ^+ . This reproduces or strengthens results from [7, 10, 11] under a unified framework, with simpler proofs. In particular, we produce a tighter bound on the entanglement assisted independence number: $\alpha^* \leq \vartheta^-$.

The technical results, Theorems 6 and 10, should be accessible to the reader who is familiar with graph theory but not information theory or quantum mechanics, which merely provide a motivation for the problem.

II. SOURCE-CHANNEL CODING

We will make use of the following graph theoretical concepts. A *graph* G consists of a set of *vertices* $V(G)$ along with a symmetric binary relation $x \sim_G y$ among vertices (we abbreviate $x \sim y$ when the graph can be inferred from context). A pair of vertices (x, y) satisfying $x \sim y$ are said to be *adjacent*. Equivalently, it is said that there is an *edge* between x and y . Vertices are not adjacent to themselves, so $x \not\sim x$ for all $x \in V(G)$. The *complement* of a graph G , denoted $\overline{G}$, has the same set of vertices but has edges between distinct pairs of vertices which are not adjacent in G (i.e. for $x \neq y$ we have $x \sim_{\overline{G}} y \iff x \not\sim_G y$). A set of vertices no two of which form an edge is known as an *independent set*; the size of the largest independent set is the *independence number* $\alpha(G)$. A set of vertices such that every pair is adjacent is known as a *clique*; the size of the largest clique is the *clique number* $\omega(G)$. Clearly $\omega(G) = \alpha(\overline{G})$. An assignment of colors to vertices such that adjacent vertices are given distinct colors is called a *proper coloring*; the minimum number of colors needed is the *chromatic number* $\chi(G)$. A function mapping the vertices of one graph to those of another, $f : V(G) \rightarrow V(H)$, is a *homomorphism* if $x \sim_G y \implies f(x) \sim_H f(y)$. Since vertices are not adjacent to themselves it is necessary that $f(x) \neq f(y)$ when $x \sim y$. If such a function exists, we say that G is *homomorphic* to H and write $G \rightarrow H$. The *complete graph* on n vertices, denoted K_n , has an edge between every pair of vertices. It is not hard to see that $\omega(G)$ is equal to the largest n such that $K_n \rightarrow G$, and $\chi(G)$ is equal to the smallest n such that $G \rightarrow K_n$. Many other graph properties can be expressed in terms of homomorphisms; for details see [12, 13]. The *strong product* of two graphs, $G \boxtimes H$, has vertex set $V(G) \times V(H)$ and has edges

$$(x_1, y_1) \sim (x_2, y_2) \iff (x_1 = x_2 \text{ and } y_1 \sim y_2) \text{ or } (x_1 \sim x_2 \text{ and } y_1 = y_2) \text{ or } (x_1 \sim x_2 \text{ and } y_1 \sim y_2).$$

The n -fold strong product is written $G^{\boxtimes n} := G \boxtimes G \boxtimes \dots \boxtimes G$. The *disjunctive product* $G * H$ has edges

$$(x_1, y_1) \sim (x_2, y_2) \iff x_1 \sim x_2 \text{ or } y_1 \sim y_2.$$

It is easy to see that $\overline{G * H} = \overline{G} \boxtimes \overline{H}$. The n -fold disjunctive product is written $G^{*n} := G * G * \dots * G$.

Suppose that Alice communicates to Bob through a noisy classical channel $\mathcal{N} : S \rightarrow V$. She wishes to send a message to Bob with zero chance of error. Let $\mathcal{N}(v|s)$ denote the probability that $\mathcal{N}$ will produce symbol v when given symbol s as input, and define the graph H with vertices S and edges

$$s \sim_H t \iff \mathcal{N}(v|s)\mathcal{N}(v|t) = 0 \text{ for all } v \in V. \quad (1)$$

Bob can distinguish codewords s and t if and only if they have no chance of being mapped to the same output by $\mathcal{N}$. Therefore, Alice's set of codewords must form a clique of H ; the size of the largest such set is the clique number $\omega(H)$. The complementary graph $\overline{H}$ is known as the *confusability graph* of $\mathcal{N}$. Note that standard convention is to denote the confusability graph by H rather than $\overline{H}$. We break convention in order to make notation in this paper much simpler. However, to minimize confusion when discussing prior results, we will follow the tradition of using the independence number when speaking of the number of codewords that Alice can send (equal to $\alpha(\overline{H}) = \omega(H)$ in our notation).

The number of bits (the base-2 log of the number of distinct messages) that Alice can send with a single use of $\mathcal{N}$ is known as the *one-shot zero-error capacity* of $\mathcal{N}$, and is equal to $\log \alpha(\overline{H})$. The average number of bits that can be sent per channel use (again with zero error) in the limit of many uses of a channel is known as the *Shannon capacity*. With n parallel uses of $\mathcal{N}$ the complement of the confusability graph is H^{*n} . The Shannon capacity of $\mathcal{N}$ is therefore

$$\begin{aligned} \Theta(\overline{H}) &:= \lim_{n \rightarrow \infty} \frac{1}{n} \log \omega(H^{*n}) \\ &= \lim_{n \rightarrow \infty} \frac{1}{n} \log \alpha(\overline{H}^{\boxtimes n}). \end{aligned}$$

This quantity is in general very difficult to compute, with the capacity of the five cycle graph $\overline{H} = C_5$ having been open for over 20 years and the capacity of C_7 being unknown to this day. The capacity of C_5 was solved by Lovász [4] who introduced a function $\vartheta(\overline{H})$, the definition of which will be postponed until Section III. Lovász proved a sandwich theorem which, using the notation $\overline{\vartheta}(H) := \vartheta(\overline{H})$, takes the form

$$\alpha(\overline{H}) = \omega(H) \leq \overline{\vartheta}(H) \leq \chi(H).$$

He also showed that $\overline{\vartheta}(H^{*n}) = \overline{\vartheta}(H)^n$, therefore $\Theta(\overline{H}) \leq \overline{\vartheta}(H)$. This bound also applies to entanglement assisted communication [7], which we will investigate in detail, and has been generalized to quantum channels [8, 9].

FIG. 1. A zero-error source-channel (1,1)-coding scheme.

We now introduce the *source-channel coding* problem. As before, Alice wishes to send Bob a message $x \in X$, and she can only communicate through a noisy channel $\mathcal{N} : S \rightarrow V$. Now, however, Bob has some side information about Alice's message. Specifically, Alice and Bob each receive one part of a pair (x, u) drawn according to a probability distribution $P(x, u)$. This is known as a *dual source*. Alice encodes her input x using a function $f : X \rightarrow S$ and sends the result through $\mathcal{N}$. Bob must deduce x with zero chance of error using the output of $\mathcal{N}$ along with his side information u . Such a protocol is called a *zero-error source-channel (1,1)-coding scheme*, and is depicted in Fig. 1. An (m, n) -coding scheme transmits m independent instances of the source using n copies of the channel.

Again the analysis involves graphs. Let H again be the complement of the confusability graph (1) and define the *characteristic graph* G with vertices X and edges

$$x \sim_G y \iff \exists u \in U \text{ such that } P(x, u)P(y, u) \neq 0.$$

In [3] it was shown that decoding is possible if and only if Alice's encoding f is a homomorphism from G to H .¹ Therefore a zero-error $(1, 1)$ -coding scheme exists if and only if $G \rightarrow H$. A zero-error (m, n) -coding scheme is possible if and only if

$$G^{\boxtimes m} \rightarrow H^{*n}. \quad (2)$$

The smallest possible ratio n/m (in the limit $m \rightarrow \infty$) is called the *cost rate*, $\eta(G, \overline{H})$. More precisely, the cost rate is defined as

$$\eta(G, \overline{H}) = \lim_{m \rightarrow \infty} \frac{1}{m} \min \left\{ n : G^{\boxtimes m} \rightarrow H^{*n} \right\}. \quad (3)$$

The $\overline{\vartheta}$ quantity is monotone under graph homomorphisms in the sense that $G \rightarrow H \implies \overline{\vartheta}(G) \leq \overline{\vartheta}(H)$ [14]. Consequently, a zero-error $(1, 1)$ -coding scheme requires $\overline{\vartheta}(G) \leq \overline{\vartheta}(H)$. Since $\overline{\vartheta}(G^{\boxtimes m}) = \overline{\vartheta}(G)^m$ [15] and $\overline{\vartheta}(H^{*n}) = \overline{\vartheta}(H)^n$ [4], it follows that an (m, n) -coding scheme is possible only if $\log \overline{\vartheta}(G) / \log \overline{\vartheta}(H) \leq n/m$. Thus we have the bound

$$\eta(G, \overline{H}) \geq \frac{\log \overline{\vartheta}(G)}{\log \overline{\vartheta}(H)}.$$

(Cf. [3] for the special case of the Witsenhausen rate.)

We will return to this in Section III when we prove an analogous bound for entanglement assisted zero-error source-channel coding.

When Bob has no side information (equivalently, when U is a singleton), G is the complete graph. In this case zero-error transmission of x is possible if and only if $K_n \rightarrow H$ where $n = |X|$, which in turn holds if and only if $n \leq \omega(H) = \alpha(\overline{H})$. This is the expected result, since as mentioned before $\alpha(\overline{H})$ is the number of unambiguously decodable codewords that Alice can send through $\mathcal{N}$. On the other hand, consider the case where there is side information and $\mathcal{N}$ is a noiseless channel of size $n = |S|$. Now H becomes the complete graph K_n , so x can be perfectly transmitted if and only if $G \rightarrow K_n$. This holds if and only if $n \geq \chi(G)$. These two examples provide an operational interpretation to the independence number and chromatic number of a graph. The analogous communication problems in the presence of an entangled state (which we examine shortly) define the entanglement assisted independence and chromatic numbers.

FIG. 2. An entanglement assisted zero-error source-channel $(1, 1)$ -coding scheme.

If Alice and Bob share an entangled state they can use the strategy depicted in Fig. 2, which is described in greater detail in [10]. Alice, upon receiving $x \in X$, performs a POVM $\{M_s^x\}_{s \in S}$ on her half of the entanglement resource $|\psi\rangle \in \mathcal{H}_A \otimes \mathcal{H}_B$ and receives measurement outcome $s \in S$. Without loss of generality

¹ Basically, G represents the information that needs to be sent and H represents the information that survives the channel. A homomorphism $G \rightarrow H$ ensures that the needed information makes it through the channel intact.

this can be assumed to be a projective measurement since any POVM can be converted to a projective measurement by enlarging the entangled state. So for each $x \in X$, the collection $\{M_s^x\}_{s \in S}$ consists of projectors on $\mathcal{H}_A$ which sum to the identity. Alice sends the measurement outcome s through the channel $\mathcal{N}$ to Bob, who receives some $v \in V$ such that $\mathcal{N}(v|s) > 0$. Bob then measures his half of the entangled state using a projective measurement depending on v and his side information u . An *entanglement assisted zero-error (1,1)-coding scheme* is one in which Bob is able to determine x with zero chance of error; an *entanglement assisted zero-error (m,n)-coding scheme* involves sending m independent samples of the source using n copies of the channel.

After Alice's measurement, Bob's half of the entanglement resource is in the state

$$\rho_s^x = \text{Tr}_A\{(M_s^x \otimes I)|\psi\rangle\langle\psi|\}.$$

An error free decoding operation exists for Bob if and only if these states are orthogonal for every $x \in X$ consistent with the information in Bob's possession (i.e. u and v). We then have the following necessary and sufficient condition [10]. Let G be the characteristic graph of the source and H be the complement of the confusability graph of the channel. There must be a bipartite pure state $|\psi\rangle \in \mathcal{H}_A \otimes \mathcal{H}_B$ for some Hilbert spaces $\mathcal{H}_A$ and $\mathcal{H}_B$, and for each $x \in X$ there must be a projective decomposition of the identity $\{M_s^x\}_{s \in S}$ on $\mathcal{H}_A$ such that

$$\rho_s^x \perp \rho_t^y \text{ for all } x \sim_G y \text{ and } s \not\sim_H t,$$

where orthogonality is in terms of the Hilbert-Schmidt inner product.

Recall that without entanglement a zero-error (1,1)-coding scheme was possible if and only if $G \rightarrow H$. By analogy we say there is an *entanglement assisted homomorphism* $G \xrightarrow{*} H$ when there exists an entanglement assisted zero-error (1,1)-coding scheme:

Definition 1. Let G and H be graphs. There is an *entanglement assisted homomorphism* from G to H , written $G \xrightarrow{*} H$, if there is a bipartite state $|\psi\rangle \in \mathcal{H}_A \otimes \mathcal{H}_B$ (for some Hilbert spaces $\mathcal{H}_A$ and $\mathcal{H}_B$) and, for each $x \in V(G)$, a projective decomposition of the identity $\{M_s^x\}_{s \in V(H)}$ on $\mathcal{H}_A$ such that

$$\rho_s^x \perp \rho_t^y \text{ for all } x \sim_G y \text{ and } s \not\sim_H t, \quad (4)$$

where

$$\rho_s^x := \text{Tr}_A\{(M_s^x \otimes I)|\psi\rangle\langle\psi|\}. \quad (5)$$

Analogous to (2), there is an entanglement assisted (m,n) -coding scheme if and only if $G^{\boxtimes m} \xrightarrow{*} H^{*n}$. The entangled cost rate [10] is analogous to (3),

$$\eta^*(G, \overline{H}) = \lim_{m \rightarrow \infty} \frac{1}{m} \min \left\{ n : G^{\boxtimes m} \xrightarrow{*} H^{*n} \right\}. \quad (6)$$

In the absence of side information (i.e. with U being a singleton set), G becomes the complete graph. We saw above that without entanglement and without side information, n distinct codewords can be sent error-free through a noisy channel if and only if $K_n \rightarrow H$; the largest such n is $\omega(H) = \alpha(\overline{H})$. With the help of entanglement the largest number of codewords is the largest n such that $K_n \xrightarrow{*} H$; this defines the *entanglement assisted independence number*, $\alpha^*(\overline{H})$. Since an entanglement resource never hurts, $\alpha^*(\overline{H}) \geq \alpha(\overline{H})$ always. In some cases $\alpha^*(\overline{H})$ can be strictly larger than $\alpha(\overline{H})$ [5].

We saw above that $\alpha(\overline{H}) \leq \overline{\vartheta}(H)$. Indeed, this was the original application of $\overline{\vartheta}$. Beigi showed that also $\alpha^*(\overline{H}) \leq \overline{\vartheta}(H)$ [7] (this has been generalized to quantum channels as well [8, 9]; however, we consider here only classical channels). Beigi proved his bound by showing that if n distinct messages can be sent through a noisy channel with zero-error using entanglement ($K_n \xrightarrow{*} H$ in our notation) then there are vectors $|w\rangle \neq 0$ and $|w_s^x\rangle$ with $x \in \{1, \dots, n\}$ and $s \in V(H)$ such that²

$$\sum_s |w_s^x\rangle = |w\rangle \quad (7)$$

$$\langle w_s^x | w_t^y \rangle = 0 \text{ for all } x \neq y, s \not\sim_H t \quad (8)$$

$$\langle w_s^x | w_t^x \rangle = 0 \text{ for all } s \neq t. \quad (9)$$

² Recall that we take $\overline{H}$ to be the confusability graph rather than H . So Beigi's definition is worded differently.

Denote by $\beta(\overline{H})$ the largest n such that vectors of this form exist. Then $\beta(\overline{H}) \geq \alpha^*(\overline{H})$. Beigi showed that the existence of such vectors implies $n \leq \overline{\vartheta}(H)$, therefore $\alpha^*(\overline{H}) \leq \beta(\overline{H}) \leq \overline{\vartheta}(H)$. Since ϑ is multiplicative under the strong graph product, $\overline{\vartheta}(H)$ is in fact an upper bound on the entanglement assisted Shannon capacity. Beigi left open the question of whether $\beta(\overline{H})$ was equal to $\lfloor \overline{\vartheta}(H) \rfloor$. We will answer this question in the affirmative (Corollary 7).

In fact, we show something more general. We generalize Beigi's vectors so that they apply to the source-channel coding problem (i.e. with G not necessarily being K_n) and give a bound in terms of the Lovász ϑ number. The conditions we will introduce can be thought of as a relaxation of the condition (4), which defines $G \xrightarrow{*} H$. A related but different relaxation will give bounds in terms of two variations of the Lovász number: the Schrijver number [16, 17] and the Szegedy number [18]. We denote the first relaxation $G \xrightarrow{B} H$ since it generalizes Beigi's condition, and denote the second $G \xrightarrow{\pm} H$ since it contains a positivity condition.

Definition 2. Let G and H be graphs. Write $G \xrightarrow{B} H$ if there are vectors $|w\rangle \neq 0$ and $|w_s^x\rangle \in \mathbb{C}^d$ for each $x \in V(G)$, $s \in V(H)$, for some $d \in \mathbb{N}$, such that

1. $\sum_s |w_s^x\rangle = |w\rangle$
2. $\langle w_s^x | w_t^y \rangle = 0$ for all $x \sim_G y$, $s \not\sim_H t$
3. $\langle w_s^x | w_t^x \rangle = 0$ for all $s \neq t$.

Definition 3. Let G and H be graphs. Write $G \xrightarrow{\pm} H$ if there are vectors $|w\rangle \neq 0$ and $|w_s^x\rangle \in \mathbb{C}^d$ for each $x \in V(G)$, $s \in V(H)$, for some $d \in \mathbb{N}$, such that

1. $\sum_s |w_s^x\rangle = |w\rangle$
2. $\langle w_s^x | w_t^y \rangle = 0$ for all $x \sim_G y$, $s \not\sim_H t$
3. $\langle w_s^x | w_t^y \rangle \geq 0$.

Note that without loss of generality one could consider only real vectors, since complex vectors can be turned real via the recipe $|\hat{w}_s^x\rangle = \text{Re}(|w_s^x\rangle) \oplus \text{Im}(|w_s^x\rangle)$ while preserving the inner product properties required by the above definitions.

We now show that $G \xrightarrow{B} H$ and $G \xrightarrow{\pm} H$ are indeed relaxations of $G \xrightarrow{*} H$. Since Definition 2 reduces to Beigi's criteria when considering $K_n \xrightarrow{B} H$, the argument that follows provides an alternative and simpler proof of Beigi's result that $\alpha^*(\overline{H}) \leq \beta(\overline{H})$.

Theorem 4. If $G \xrightarrow{*} H$ then $G \xrightarrow{B} H$ and $G \xrightarrow{\pm} H$.

Proof. ($G \xrightarrow{*} H \implies G \xrightarrow{B} H$): Suppose that $G \xrightarrow{*} H$. Let $|\psi\rangle$ and M_s^x for $x \in V(G)$ and $s \in V(H)$ satisfy condition (4) (with ρ_s^x given by (5)). Define $|w\rangle = |\psi\rangle$ and

$$|w_s^x\rangle = (M_s^x \otimes I) |\psi\rangle.$$

Since $\{M_s^x\}_{s \in S}$ is a projective decomposition of the identity,

$$\begin{aligned} \sum_s M_s^x &= I \implies \sum_s |w_s^x\rangle = |w\rangle, \\ M_s^x M_t^x &= 0 \implies \langle w_s^x | w_t^x \rangle = 0 \text{ for } s \neq t. \end{aligned}$$

For all $x \sim_G y$ and $s \not\sim_H t$, condition (4) gives that the reduced density operators (tracing over $\mathcal{H}_A$) of the post-measurement states $(M_s^x \otimes I) |\psi\rangle$ and $(M_t^y \otimes I) |\psi\rangle$ are orthogonal. But this is only possible if the pure states (without tracing out $\mathcal{H}_A$) are orthogonal. So,

$$\langle \psi | (M_s^x \otimes I)^\dagger (M_t^y \otimes I) | \psi \rangle = 0 \implies \langle w_s^x | w_t^y \rangle = 0.$$

($G \xrightarrow{*} H \implies G \xrightarrow{\pm} H$): Suppose that $G \xrightarrow{*} H$. Let $|\psi\rangle$ and M_s^x for $x \in V(G)$ and $s \in V(H)$ satisfy condition (4) (with ρ_s^x given by (5)). Define $|w_s^x\rangle$ to be the vectorization of the post-measurement reduced density operator,

$$|w_s^x\rangle = \text{vec}(\rho_s^x).$$

Since $\{M_s^x\}_{s \in S}$ sum to identity,

$$\begin{aligned} \sum_s |w_s^x\rangle &= \text{vec} \left(\sum_s \text{Tr}_A \{ (M_s^x \otimes I) |\psi\rangle \langle \psi| \} \right) \\ &= \text{vec}(\text{Tr}_A \{ |\psi\rangle \langle \psi| \}) =: |w\rangle. \end{aligned}$$

For all $x \sim_G y$ and $s \not\sim_H t$, condition (4) gives $\langle w_s^x | w_t^y \rangle = 0$. Density operators are positive, giving positive inner products $\langle w_s^x | w_t^y \rangle \geq 0$. $\square$

III. MONOTONICITY THEOREMS

Our main results concern monotonicity properties of the Lovász number ϑ , Schrijver number ϑ^- , and Szegedy number ϑ^+ for graphs that are related by the generalized homomorphisms of Definitions 2 and 3. These will lead to various bounds relevant to entanglement assisted zero-error source-channel coding. These three quantities are defined as follows.

Definition 5. *In this definition we use real matrices. For convenience we state the definitions in terms of the complement of a graph, since this form is used throughout the theorems*

The Lovász number of the complement, $\bar{\vartheta}(G) := \vartheta(\bar{G})$, is given by either of the following two semidefinite programs, which are equivalent [4, 15]:

$$\begin{aligned} \bar{\vartheta}(G) &= \max \{ \|I + T\| : I + T \succeq 0, \\ &\quad T_{ij} = 0 \text{ for } i \not\sim j \}, \end{aligned} \tag{10}$$

$$\begin{aligned} \bar{\vartheta}(G) &= \min \{ \lambda : \exists Z \succeq 0, Z_{ii} = \lambda - 1, \\ &\quad Z_{ij} = -1 \text{ for } i \sim j \}, \end{aligned} \tag{11}$$

where $\|\cdot\|$ denotes the operator norm (the largest singular value) and $\succeq 0$ means that a matrix is positive semidefinite. The Schrijver number of the complement, $\bar{\vartheta}^-(G) := \vartheta^-(\bar{G})$, (sometimes written ϑ') is [16, 17]

$$\begin{aligned} \bar{\vartheta}^-(G) &= \min \{ \lambda : \exists Z \succeq 0, Z_{ii} = \lambda - 1, \\ &\quad Z_{ij} \leq -1 \text{ for } i \sim j \}. \end{aligned} \tag{12}$$

The Szegedy number of the complement, $\bar{\vartheta}^+(G) := \vartheta^+(\bar{G})$, is [18]

$$\begin{aligned} \bar{\vartheta}^+(G) &= \min \{ \lambda : \exists Z \succeq 0, Z_{ii} = \lambda - 1, \\ &\quad Z_{ij} = -1 \text{ for } i \sim j, \\ &\quad Z_{ij} \geq -1 \text{ for all } i, j \}. \end{aligned} \tag{13}$$

Clearly $\bar{\vartheta}^-(G) \leq \bar{\vartheta}(G) \leq \bar{\vartheta}^+(G)$.

Our first result is that the generalized homomorphism of Definition 2 exactly characterizes ordering of $\bar{\vartheta}$. This will lead to a bound on entanglement assisted cost rate.

Theorem 6. $G \xrightarrow{B} H \iff \bar{\vartheta}(G) \leq \bar{\vartheta}(H)$.

Proof. Before beginning the proof, it will be useful to reformulate the conditions of Definition 2 in terms of the Gram matrix of the vectors $|w_s^x\rangle$. Note that without loss of generality we can rescale so that $\langle w | w \rangle = 1$. Define the matrix $C : \mathcal{L}(\mathbb{C}^{|V(G)|}) \otimes \mathcal{L}(\mathbb{C}^{|V(H)|})$ with entries $C_{xyst} = \langle w_s^x | w_t^y \rangle$ for $x, y \in V(G)$ and $s, t \in V(H)$. If the $|w_s^x\rangle$ satisfy the properties of Definition 2 then C satisfies

$$C \succeq 0 \tag{14}$$

$$\sum_{st} C_{xyst} = 1 \tag{15}$$

$$C_{xyst} = 0 \text{ for } x \sim_G y \text{ and } s \not\sim_H t \tag{16}$$

$$C_{xxst} = 0 \text{ for } s \neq t. \tag{17}$$

It is easy to see that the implication goes the other way as well (i.e. the existence of such a C implies $G \xrightarrow{B} H$), with the only nontrivial implication being $\sum_{st} C_{xyst} = 1 \implies \sum_s |w_s^x\rangle = |w\rangle$ for some normalized vector $|w\rangle$. We have that for all $x, y \in V(G)$,

$$1 = \sum_{st} C_{xyst} = \sum_{st} \langle w_s^x | w_t^y \rangle = \left(\sum_s \langle w_s^x | \right) \left(\sum_t |w_t^y\rangle \right).$$

But this is only possible if $\sum_s |w_s^x\rangle$ is the same vector for all $x \in V(G)$. Call this $|w\rangle$. Clearly $|w\rangle \neq 0$. Using this alternative formulation of Definition 2, we proceed with the proof.

($\Leftarrow$): Suppose $\bar{\vartheta}(G) \leq \bar{\vartheta}(H)$. We will explicitly construct a matrix C having the above properties. Let $\lambda = \bar{\vartheta}(H)$. By definition, there is a matrix T such that $\|I + T\| = \lambda$, $I + T \succeq 0$, and $T_{st} = 0$ for $s \not\sim t$. With $|\psi\rangle$ denoting the vector corresponding to the largest eigenvalue of $I + T$, and with $\circ$ denoting the Schur-Hadamard (i.e. entrywise) product, define the matrices

$$\begin{aligned} D &= |\psi\rangle \langle \psi| \circ I, \\ B &= |\psi\rangle \langle \psi| \circ (I + T). \end{aligned}$$

With J being the all-ones matrix and $\langle \cdot, \cdot \rangle$ denoting the Hilbert-Schmidt inner product, it is readily verified that

$$\begin{aligned} \langle D, J \rangle &= \langle \psi | \psi \rangle = 1, \\ \langle B, J \rangle &= \langle \psi | I + T | \psi \rangle = \lambda. \end{aligned}$$

Schur-Hadamard products between positive semidefinite matrices yield positive semidefinite matrices. As a consequence, $B \succeq 0$ and

$$\|I + T\| = \lambda \implies \lambda I - (I + T) \succeq 0 \implies \lambda D - B \succeq 0.$$

Since $\lambda \geq \bar{\vartheta}(G)$, there is a matrix Z such that $Z \succeq 0$, $Z_{xx} = \lambda - 1$ for all x , and $Z_{xy} = -1$ for all $x \sim_G y$. Note that Definition 5 gives existence of a matrix with $\bar{\vartheta}(G) - 1$ on the diagonal, but since $\lambda \geq \bar{\vartheta}(G)$ we can add a multiple of the identity to get $\lambda - 1$ on the diagonal.

We now construct C . Define

$$C = \lambda^{-1} [J \otimes B + (\lambda - 1)^{-1} Z \otimes (\lambda D - B)].$$

Since J , B , Z , and $\lambda D - B$ are all positive semidefinite, and $\lambda - 1 \geq 0$, we have that C is positive semidefinite. The other desired conditions on C are easy to verify. For all x, y we have

$$\begin{aligned} \sum_{st} C_{xyst} &= \lambda^{-1} [J_{xy} \langle B, J \rangle + (\lambda - 1)^{-1} Z_{xy} [\lambda \langle D, J \rangle - \langle B, J \rangle]] \\ &= J_{xy} = 1. \end{aligned}$$

For $x \sim_G y$ and $s \not\sim_H t$,

$$\begin{aligned} C_{xyst} &= \lambda^{-1} [J_{xy} B_{st} + (\lambda - 1)^{-1} Z_{xy} (\lambda D_{st} - B_{st})] \\ &= \lambda^{-1} [B_{st} + (\lambda - 1)^{-1} (-1) (\lambda D_{st} - B_{st})] \\ &= \lambda^{-1} [B_{st} + (\lambda - 1)^{-1} (-1) (\lambda B_{st} - B_{st})] \\ &= 0. \end{aligned}$$

For all x and for $s \neq t$,

$$\begin{aligned} C_{xxst} &= \lambda^{-1} [J_{xx} B_{st} + (\lambda - 1)^{-1} Z_{xx} (\lambda D_{st} - B_{st})] \\ &= \lambda^{-1} [B_{st} + (0 - B_{st})] \\ &= 0. \end{aligned}$$

($\implies$): Suppose $G \xrightarrow{B} H$. There there is a matrix C satisfying properties (14)-(17). Let Z achieve the optimal value (call it λ) for the minimization (11) for $\bar{\vartheta}(H)$. We will provide a feasible solution for (11) for $\bar{\vartheta}(G)$ to show that $\bar{\vartheta}(G) \leq \lambda = \bar{\vartheta}(H)$. To this end, define

$$Y_{xy} = \sum_{st} Z_{st} C_{xyst}.$$

$C \succeq 0$ and $Z \succeq 0$, so by Choi's theorem on completely positive maps $Y \succeq 0$. Using the fact that $Z_{ss} = \lambda - 1$ and $C_{xxst} = 0$ for $s \neq t$, we have

$$Y_{xx} = \sum_{st} Z_{st} C_{xxst} = (\lambda - 1) \sum_{st} C_{xxst} = \lambda - 1.$$

Using the fact that $Z_{st} = -1$ for $s \sim_H t$ and $C_{xyst} = 0$ for $x \sim_G y$, $s \not\sim_H t$, we have that for $x \sim_G y$,

$$Y_{xy} = \sum_{st} Z_{st} C_{xyst} = \sum_{s \sim_H t} Z_{st} C_{xyst} = (-1) \sum_{s \sim_H t} C_{xyst} = (-1) \sum_{st} C_{xyst} = -1.$$

Now define a matrix Y' consisting of the real part of Y (i.e. with coefficients $Y'_{xy} = \text{Re}[Y_{xy}]$). This matrix is real, positive semidefinite,³ and satisfies $Y'_{xx} = \lambda - 1$ for all x and $Y'_{xy} = -1$ for $x \sim y$. Therefore Y' is feasible for (11) with value $\lambda = \bar{\vartheta}(H)$. Since $\bar{\vartheta}(G)$ is the minimum possible value of (11), we have $\bar{\vartheta}(G) \leq \bar{\vartheta}(H)$. $\square$

We are now prepared to answer in the affirmative an open question posed by Beigi [7].

Corollary 7. *Let $\beta(\bar{H})$ be the largest n such that there exist vectors $|w\rangle \neq 0$ and $|w_s^x\rangle$ with $x \in \{1, \dots, n\}$ and $s \in V(H)$ which satisfy conditions (7)-(9). Then $\beta(\bar{H}) = \lfloor \bar{\vartheta}(H) \rfloor$.*

Proof. Considering $K_n \xrightarrow{B} H$, the conditions of Definition 2 are equivalent to (7)-(9). Since $\bar{\vartheta}(K_n) = n$, Theorem 6 gives $K_n \xrightarrow{B} H \iff n \leq \bar{\vartheta}(H)$. Since $\beta(\bar{H})$ is the largest n such that $K_n \xrightarrow{B} H$, we have that $\beta(\bar{H}) = \lfloor \bar{\vartheta}(H) \rfloor$. $\square$

A related corollary can be formed by considering $G \xrightarrow{B} K_n$ rather than $K_n \xrightarrow{B} \bar{H}$. This defines a set of vectors $|w_s^x\rangle$ satisfying conditions in some sense complementary to Beigi's (7)-(9). Now we approach ϑ from above:

Corollary 8. *Let $\beta_\chi(G)$ be the smallest n such that there exist vectors $|w\rangle \neq 0$ and $|w_s^x\rangle$ with $x \in V(G)$ and $s \in \{1, \dots, n\}$ for which*

1. $\sum_s |w_s^x\rangle = |w\rangle$
2. $\langle w_s^x | w_s^y \rangle = 0$ for all $x \sim_G y$
3. $\langle w_s^x | w_t^x \rangle = 0$ for all $s \neq t$.

Then $\beta_\chi(G) = \lceil \bar{\vartheta}(G) \rceil$.

Proof. Considering $G \xrightarrow{B} K_n$, the conditions of Definition 2 are equivalent to the conditions stated above. Since $\bar{\vartheta}(K_n) = n$, Theorem 6 gives $G \xrightarrow{B} K_n \iff \bar{\vartheta}(G) \leq n$. Since $\beta_\chi(G)$ is the smallest n such that $G \xrightarrow{B} K_n$, we have $\beta_\chi(G) = \lceil \bar{\vartheta}(G) \rceil$. $\square$

Corollary 9. *The entanglement assisted cost rate is bounded as follows:*

$$\eta^*(G, \bar{H}) \geq \frac{\log \bar{\vartheta}(G)}{\log \bar{\vartheta}(H)}.$$

³ The entrywise complex conjugate of a positive semidefinite matrix is positive semidefinite, so $Y' = (Y + \text{conj}(Y))/2 \succeq 0$.

Proof. Since $\bar{\vartheta}(G^{\boxtimes m}) = \bar{\vartheta}(G)^m$ [15] and $\bar{\vartheta}(H^{*n}) = \bar{\vartheta}(H)^n$ [4], it follows that

$$\begin{aligned} G^{\boxtimes m} \xrightarrow{*} H^{*n} &\implies G^{\boxtimes m} \xrightarrow{B} H^{*n} && \text{(by Theorem 4)} \\ &\implies \bar{\vartheta}(G^{\boxtimes m}) \leq \bar{\vartheta}(H^{*n}) && \text{(by Theorem 6)} \\ &\implies \bar{\vartheta}(G)^m \leq \bar{\vartheta}(H)^n \\ &\implies \frac{\log \bar{\vartheta}(G)}{\log \bar{\vartheta}(H)} \leq \frac{n}{m}. \end{aligned}$$

Therefore,

$$\eta^*(G, \bar{H}) = \lim_{m \rightarrow \infty} \min_n \left\{ \frac{n}{m} : G^{\boxtimes m} \xrightarrow{*} H^{*n} \right\} \geq \frac{\log \bar{\vartheta}(G)}{\log \bar{\vartheta}(H)}.$$

□

Something similar to Theorem 6 holds for the relation $G \xrightarrow{\pm} H$. In this case there is an inequality not just for the Lovász ϑ number but also for Schrijver's ϑ^- and Szegedy's ϑ^+ . Unfortunately, this will no longer be an if-and-only-if statement (but see Theorem 13 for a weakened converse, and Appendix B for a somewhat more complicated if-and-only-if involving $\bar{\vartheta}^-$).

Theorem 10. Suppose $G \xrightarrow{\pm} H$. Then $\bar{\vartheta}(G) \leq \bar{\vartheta}(H)$, $\bar{\vartheta}^-(G) \leq \bar{\vartheta}^-(H)$, and $\bar{\vartheta}^+(G) \leq \bar{\vartheta}^+(H)$.

Proof. Again we will use the Gram matrix of the $|w_s^x\rangle$ vectors, again assuming without loss of generality that $\langle w|w\rangle = 1$. Defining $C_{xyst} = \langle w_s^x | w_t^y \rangle$ for $x, y \in V(G)$ and $s, t \in V(H)$, we have that $G \xrightarrow{\pm} H$ implies

$$\begin{aligned} C &\succeq 0 \\ \sum_{st} C_{xyst} &= 1 \\ C_{xyst} &= 0 \text{ for } x \sim_G y \text{ and } s \not\sim_H t \\ C_{xyst} &\geq 0. \end{aligned}$$

We give the proof for $\bar{\vartheta}^-(G) \leq \bar{\vartheta}^-(H)$; the others are proved in a similar way. The proof is very similar to that of Theorem 6, with slight modification due to the fact that the last condition on C is different. Let Z achieve the optimal value for the minimization program (12) for $\bar{\vartheta}^-(H)$. We will provide a feasible solution for (12) for $\bar{\vartheta}^-(G)$ to show that $\bar{\vartheta}^-(G) \leq \bar{\vartheta}^-(H)$. Specifically, let $Y_{xy} = \sum_{st} Z_{st} C_{xyst}$. Since C and Z are positive semidefinite, so is Y .

A feasible solution for (12), with value $\bar{\vartheta}^-(H)$, requires $Y_{xx} = \bar{\vartheta}^-(H) - 1$. However, it suffices to show $Y_{xx} \leq \bar{\vartheta}^-(H) - 1$ since equality can be achieved by adding a non-negative diagonal matrix to Y . We have

$$\begin{aligned} Y_{xx} &= \sum_{st} Z_{st} C_{xxst} \\ &\leq \max_{st} |Z_{st}| \sum_{st} C_{xxst} && \text{(since } C_{xxst} \geq 0) \\ &\leq \max_s |Z_{ss}| \sum_{st} C_{xxst} && \text{(since } Z \succeq 0) \\ &= \bar{\vartheta}^-(H) - 1. \end{aligned}$$

Similarly, for $x \sim_G y$ we have

$$Y_{xy} = \sum_{st} Z_{st} C_{xyst} = \sum_{s \sim_H t} Z_{st} C_{xyst} \leq (-1) \sum_{s \sim_H t} C_{xyst} = (-1) \sum_{st} C_{xyst} = -1. \quad (18)$$

Therefore Y is feasible for (12) with value $\lambda = \bar{\vartheta}^-(H)$. Since $\bar{\vartheta}^-(G)$ is the minimum possible value of (12), we have $\bar{\vartheta}^-(G) \leq \bar{\vartheta}^-(H)$.

To show $\bar{\vartheta}(G) \leq \bar{\vartheta}(H)$ or $\bar{\vartheta}^+(G) \leq \bar{\vartheta}^+(H)$, replace inequality with equality in (18). For $\bar{\vartheta}^+(G) \leq \bar{\vartheta}^+(H)$ we have $Z_{st} \geq -1$ for all s, t and need to show $Y_{xy} \geq -1$ for all x, y . This is readily verified:

$$Y_{xy} = \sum_{st} Z_{st} C_{xyst} \geq (-1) \sum_{st} C_{xyst} = 1.$$

□

It is well known that $\alpha(G) \leq \vartheta^-(G) \leq \vartheta(G) \leq \vartheta^+(G) \leq \chi(\overline{G})$. We show that similar inequalities hold for the entanglement assisted independence and chromatic numbers. Since ϑ^- and ϑ^+ are not multiplicative under the required graph products (Appendix A), these do not lead to bounds on asymptotic quantities such as entanglement assisted Shannon capacity or entanglement assisted cost rate.

Corollary 11. $\alpha^*(H) \leq \vartheta^-(H)$.

Proof. By definition $\alpha^*(H)$ is the largest n such that $K_n \xrightarrow{*} \overline{H}$. But $K_n \xrightarrow{*} \overline{H} \implies K_n \xrightarrow{+} \overline{H} \implies \bar{\vartheta}^-(K_n) \leq \bar{\vartheta}^-(H)$. Since $\bar{\vartheta}^-(K_n) = n$, the conclusion follows. □

Corollary 12. Define $\chi^*(G)$ to be the smallest n such that $G \xrightarrow{*} K_n$. Then $\chi^*(G) \geq \bar{\vartheta}^+(G)$. This was already shown in [10].

Proof. By definition, $\chi^*(G)$ is the smallest n such that $G \xrightarrow{*} K_n$. But $G \xrightarrow{*} K_n \implies G \xrightarrow{+} K_n \implies \bar{\vartheta}^+(G) \leq \bar{\vartheta}^+(K_n) = n$. □

It would be nice to have a converse to Theorem 10, like there was with Theorem 6. Is it the case that $\bar{\vartheta}(G) \leq \bar{\vartheta}(H)$, $\bar{\vartheta}^-(G) \leq \bar{\vartheta}^-(H)$, and $\bar{\vartheta}^+(G) \leq \bar{\vartheta}^+(H)$ together imply $G \xrightarrow{+} H$? We do not know. However, it is the case that $\bar{\vartheta}^+(G) \leq \bar{\vartheta}^-(H) \implies G \xrightarrow{+} H$. In fact, something stronger can be said. Write $G \xrightarrow{V} H$ when there are vectors $|w_s^x\rangle$ satisfying simultaneously the conditions of Definitions 2 and 3. Then we have the following theorem, which has application relating to a recent investigation into Tsirelson's conjecture in connection with quantum chromatic numbers.

Theorem 13. $\bar{\vartheta}^+(G) \leq \bar{\vartheta}^-(H) \implies G \xrightarrow{V} H$.

Proof. The proof mirrors that of the ($\Leftarrow$) portion of Theorem 6, so we only describe the differences. Let $\lambda = \bar{\vartheta}^-(H)$. By Theorem 29 in Appendix B there is a matrix T such that $\|I + T\| = \lambda$, $I + T \succeq 0$, $T_{st} = 0$ for $s \not\sim t$, and $T_{st} \geq 0$ for all s, t . Since $\lambda \geq \bar{\vartheta}^+(G)$, there is a matrix Z such that $Z \succeq 0$, $Z_{xx} = \lambda - 1$ for all x , $Z_{xy} = -1$ for all $x \sim_G y$, and $Z_{xy} \geq -1$ for all x, y . Note that T and Z satisfy all conditions required by Theorem 6 plus the additional conditions $T_{st} \geq 0$ for all s, t and $Z_{xy} \geq -1$ for all x, y .

Define B and D as in Theorem 6. Since the eigenvector $|\psi\rangle$ corresponding to the maximum eigenvalue of $I + T$ can be chosen to be entrywise non-negative, it follows that B can be chosen entrywise non-negative. As before, define

$$C = \lambda^{-1} [J \otimes B + (\lambda - 1)^{-1} Z \otimes (\lambda D - B)].$$

Since T and Z satisfy all conditions needed by Theorem 6, C satisfies (14)-(17). To get $G \xrightarrow{V} H$ it remains only to show the additional condition $C_{xyst} \geq 0$ for all x, y, s, t . When $s = t$,

$$\begin{aligned} C_{xyss} &= \lambda^{-1} [D_{ss} + (\lambda - 1)^{-1} Z_{xy} (\lambda D_{ss} - D_{ss})] \\ &= \lambda^{-1} (1 + Z_{xy}) D_{ss} \geq 0. \end{aligned}$$

The last inequality follows from $Z_{xy} \geq -1$ and $D_{ss} \geq 0$. When $s \neq t$,

$$\begin{aligned} C_{xyst} &= \lambda^{-1} [B_{st} + (\lambda - 1)^{-1} Z_{xy} (0 - B_{st})] \\ &= \lambda^{-1} (\lambda - 1)^{-1} [(\lambda - 1) - Z_{xy}] B_{st} \geq 0. \end{aligned}$$

The last inequality follows from $Z_{xy} \leq Z_{xx} = \lambda - 1$ (since $Z \succeq 0$) and $B_{st} \geq 0$. □

The notion of a *quantum homomorphism* (written $G \xrightarrow{q} H$) was introduced in [11]. Quantum homomorphisms are motivated by a quantum pseudo-telepathy game in which Alice and Bob, who share an entangled state but are not allowed to communicate, must provide answers to challenges in such a way that a referee who is not aware of quantum mechanics may be led to believe that $G \rightarrow H$. Specifically, Alice and Bob receive x, y and must produce s, t (using entanglement but no communication) such that

$$P(s, t|x, y) = 0 \text{ if } (s = t \text{ and } x = y) \text{ or } (x \sim_G y \text{ and } s \not\sim_H t). \quad (19)$$

This is possible if and only if there exists sets of projectors with certain properties [11], and for simplicity we take these conditions as the definition of $G \xrightarrow{q} H$.

Definition 14. *There is a quantum homomorphism between G and H (written $G \xrightarrow{q} H$) if there exist projectors P_s^x for $x \in V(G)$ and $s \in V(H)$ such that*

1. $\sum_s P_s^x = I$
2. $P_s^x P_t^y = 0$ for all $x \sim_G y, s \not\sim_H t$
3. $P_s^x P_t^x = 0$ for all $s \neq t$.

Note that the first condition actually implies the third.

Given such a collection of projectors, the homomorphism game is won by Alice using the POVM $\{P_s^x\}_s$ and Bob the POVM $\{(P_t^y)^T\}_t$ upon the maximally entangled state $|\psi\rangle = d^{-1/2} \sum_{i=1}^d |i\rangle \otimes |i\rangle$. By plugging $M_s^x = P_s^x$ into Definition 1 it is easily seen⁴ that $G \xrightarrow{*} H$ (and therefore also $G \xrightarrow{\pm} H$) so Theorem 10 gives

Corollary 15. *Suppose $G \xrightarrow{q} H$. Then $\bar{\vartheta}(G) \leq \bar{\vartheta}(H)$, $\bar{\vartheta}^-(G) \leq \bar{\vartheta}^-(H)$, and $\bar{\vartheta}^+(G) \leq \bar{\vartheta}^+(H)$. This was shown in [19].*

The relation $G \xrightarrow{V} H$ was inspired by a quantity χ_{vect} defined in [20], which in turn was motivated by an investigation into a program initiated by Tsirelson. The outcome probabilities for this nonlocal game are $P(s, t|x, y) = \langle \psi | P_s^x \otimes (P_t^y)^T | \psi \rangle$. Tsirelson noted that Bell-like games can be analyzed through a vector relaxation $|w_s^x\rangle = (P_s^x \otimes I)|\psi\rangle$,⁵ giving

$$P(s, t|x, y) = \langle w_s^x | w_t^y \rangle. \quad (20)$$

In general there would be two sets of vectors,

$$P(s, t|x, y) = \langle w_s^x | v_t^y \rangle, \quad (21)$$

but in the present situation the symmetry between Alice and Bob's POVMs gives $|v_t^y\rangle = |w_s^x\rangle$. It is easily seen that these $|w_s^x\rangle$ satisfy the requirements for $G \xrightarrow{V} H$, so we have $G \xrightarrow{q} H \implies G \xrightarrow{V} H$. In fact, $G \xrightarrow{V} H$ if and only if there is a probability distribution $P(s, t|x, y)$ that satisfies (19) (i.e. has zeros in the appropriate places) and (20) (i.e. is a Gram matrix).

Tsirelson had believed that such a process could be reversed, in the sense that a vector representation of the form (21) with the vectors being subnormalized implies that $P(s, t|x, y)$ arises from some Bell experiment (i.e. from local POVMs acting on an entangled state) [21]. This is now known to be false except for in some special cases. One may also ask whether such a program could be carried out if one only cares about the pattern of zeros in $P(s, t|x, y)$. In other words, does $G \xrightarrow{V} H \implies G \xrightarrow{q} H$? This question, among many others, was asked in [20] for the special case where H is the complete graph. Specifically, they define a quantity $\chi_{\text{vect}}(G)$ which, in our language, is the smallest n such that $G \xrightarrow{V} K_n$, and ask whether this is ever different from $\chi_q(G)$, defined as the smallest n such that $G \xrightarrow{q} K_n$. We answer this in the affirmative.⁶ One could also ask a similar question regarding $\omega_{\text{vect}}(H)$, defined as the largest n such that $K_n \xrightarrow{V} H$. Both $\chi_{\text{vect}}(G)$ and $\omega_{\text{vect}}(H)$ can be computed using Theorem 13. The gap sought by [20] follows shortly from this.

⁴ Since ρ_s^x defined by (5) is equal to the transpose of P_s^x , and since transpose preserves orthogonality, (4) becomes $P_s^x \perp P_t^y$ for $x \sim_G y$ and $s \not\sim_H t$.

⁵ In fact, this procedure does not require that Alice and Bob's operators be on distinct subsystems, only that they commute.

⁶ The first version of the present paper was posted before [20]. We later amended this paper to address the question posed in [20].

Corollary 16. $\chi_{\text{vect}}(G) = \lceil \bar{\vartheta}^+(G) \rceil$ and $\omega_{\text{vect}}(H) = \lfloor \bar{\vartheta}^-(H) \rfloor$.

Proof. Theorem 13 gives (for integer n) $\bar{\vartheta}^+(G) \leq n \implies G \xrightarrow{V} K_n$ and $n \leq \bar{\vartheta}^-(H) \implies K_n \xrightarrow{V} H$. Theorem 10 gives the converse, so $\bar{\vartheta}^+(G) \leq n \iff G \xrightarrow{V} K_n$ and $n \leq \bar{\vartheta}^-(H) \iff K_n \xrightarrow{V} H$. $\square$

Theorem 17. *There is a graph G such that $\chi_{\text{vect}}(G) < \chi_q(G)$. Therefore $G \xrightarrow{V} H$ does not imply $G \xrightarrow{q} H$.*

Proof. In light of Corollary 16, the goal is to find G such that $\lceil \bar{\vartheta}^+(G) \rceil < \chi_q(G)$. The projective rank of a graph, $\xi_f(G)$, is the infimum of d/r such that the vertices of a graph can be assigned rank- r projectors in $\mathbb{C}^d$ such that adjacent vertices have orthogonal projectors. Such an assignment is called a d/r -representation. Since $\xi_f(G) \leq \chi_q(G)$ [19], it suffices to find a gap between $\lceil \bar{\vartheta}^+(G) \rceil$ and $\xi_f(G)$.

The five cycle has $\bar{\vartheta}^+(C_5) = \sqrt{5} < \xi_f(C_5) = 5/2$ [19]. But this is not enough since $\lceil \sqrt{5} \rceil = 3 > 5/2$. Fortunately, we can amplify the difference by taking the disjunctive product with a complete graph. $\bar{\vartheta}^+$ is submultiplicative under disjunctive product. If ξ_f is multiplicative under disjunctive product then we are done since

$$\lceil \bar{\vartheta}^+(C_5 * K_3) \rceil \leq \lceil 3\sqrt{5} \rceil = 7 < 3 \cdot \frac{5}{2} = \xi_f(C_5 * K_3).$$

We will now show ξ_f to be multiplicative under both the disjunctive and the lexicographical products. The lexicographical product $G[H]$ has edges $(x, y) \sim (x', y')$ if $x \sim_G x'$ or $(x = x' \text{ and } y \sim_H y')$. A d_1/r_1 -representation for G and a d_2/r_2 -representation for H can be turned into a $d_1 d_2 / r_1 r_2$ -representation for $G * H$ by taking the tensor products of the projectors associated with each graph. So $\xi_f(G * H) \leq \xi_f(G) \xi_f(H)$.

On the other hand, let U_{xy} for $x \in V(G), y \in V(H)$ be the subspaces associated with a d/r -representation of $G[H]$. For each x , the subspaces $\{U_{xy} : y\}$ form a r'_x/r projective representation of H where r'_x is the dimension of $\text{span}\{U_{xy} : y\}$, so it must hold that $r'_x/r \geq \xi_f(H)$. Let $r' = \min\{r'_x\}$ and for each x let V_x be a r' dimensional subspace of $\text{span}\{U_{xy} : y\}$. These form a d/r' representation of G , so $d/r' \geq \xi_f(G)$. Then, $d/r = (d/r')(r'/r) \geq \xi_f(G) \xi_f(H)$ so $\xi_f(G[H]) \geq \xi_f(G) \xi_f(H)$. Since $G[H] \subseteq G * H$ we have $\xi_f(G[H]) \geq \xi_f(G) \xi_f(H) \geq \xi_f(G * H) \geq \xi_f(G[H])$, giving that ξ_f is multiplicative under both disjunctive and lexicographical products. $\square$

Finally, we show that the two conditions $G \xrightarrow{\pm} H$ and $G \xrightarrow{B} H$ are not equivalent: the second one is weaker.

Theorem 18. *If $G \xrightarrow{\pm} H$ then $G \xrightarrow{B} H$, but there are graphs for which the converse does not hold.*

Proof. The forward implication is an immediate consequence of Theorems 6 and 10:

$$G \xrightarrow{\pm} H \implies \bar{\vartheta}(G) \leq \bar{\vartheta}(H) \implies G \xrightarrow{B} H.$$

To see that the converse does not hold, take H to be any graph such that $\lfloor \bar{\vartheta}^-(H) \rfloor < \lfloor \bar{\vartheta}(H) \rfloor$. For example, a graph with $\bar{\vartheta}^-(H) = 4$ but $\bar{\vartheta}(H) = 16/3 > 5$ is given at the end of [16]. Then $5 = \bar{\vartheta}(K_5) \leq \bar{\vartheta}(H) \implies K_5 \xrightarrow{B} H$ but $5 = \bar{\vartheta}^-(K_5) > \bar{\vartheta}^-(H) \implies K_5 \not\xrightarrow{\pm} H$. $\square$

The implication relations between the various conditions investigated in this paper are summarized in Fig. 3. The only implication that we have not proved in this paper is $G \rightarrow H \implies G \xrightarrow{q} H$, which is trivial. We showed that the converse of $G \xrightarrow{\pm} H \implies G \xrightarrow{B} H$ does not hold since there is a graph with $\bar{\vartheta}(K_5) \leq \bar{\vartheta}(H)$ but $\bar{\vartheta}^-(K_5) > \bar{\vartheta}^-(H)$ (Theorem 18). [11, 22] showed that the converse of $G \rightarrow H \implies G \xrightarrow{q} H$ does not hold. We showed in Theorem 17 that the converse of $G \xrightarrow{q} H \implies G \xrightarrow{V} H$ does not hold. The converse of $\bar{\vartheta}^+(G) \leq \bar{\vartheta}^-(H) \implies G \xrightarrow{V} H$ can be seen to not hold by setting $G = H$ to any graph such that $\bar{\vartheta}^+(G) > \bar{\vartheta}^-(G)$.

Some of the possible converses are still open questions. The converse of $G \xrightarrow{q} H \implies G \xrightarrow{*} H$ holds if and only if $|\psi\rangle$ can always be taken to be the maximally entangled state in (4)-(5). In particular, a converse of $G \xrightarrow{q} H \implies G \xrightarrow{*} H$ would mean that the zero-error entanglement assisted capacity could always be achieved using a maximally entangled state along with projective measurements.

FIG. 3. Implications between various conditions discussed in this paper. Double ended arrows mean if-and-only-if, solid arrows mean the converse is known to not hold, and dotted arrows mean we do not know whether the converse holds.

IV. CONCLUSION

Beigi provided a vector relaxation of the entanglement assisted zero-error communication problem, leading to an upper bound on the entanglement assisted independence number: $\alpha^* \leq \lfloor \vartheta \rfloor$ [7]. We generalized Beigi's construction to apply it to entanglement assisted zero-error source-channel coding, defining a relaxed graph homomorphism $G \xrightarrow{B} H$. This ends up exactly characterizing monotonicity of ϑ , and shows that ϑ can be used to provide a lower bound on the cost rate for entanglement assisted source-channel coding. As a corollary we answer in the affirmative an open question posed by Beigi of whether a quantity β that he defined is equal to $\lfloor \vartheta \rfloor$. Applying a Beigi-style argument to chromatic number rather than independence number yields a quantity analogous to β which is equal to $\lceil \vartheta \rceil$. We defined a similar (and stronger) relaxation, $G \xrightarrow{\pm} H$, which yields bounds involving Schrijver's number ϑ^- and Szegedy's number ϑ^+ . This leads to a stronger bound on entanglement assisted independence number: $\alpha^* \leq \lfloor \vartheta^- \rfloor$. In addition to these new bounds, we reproduce previously known bounds from [7, 10, 11, 19].

A number of open questions remain. Since there is a graph for which $\vartheta^- < \vartheta - 1$ [16], our bound $\alpha^* \leq \lfloor \vartheta^- \rfloor$ shows a gap between one-shot entanglement assisted zero-error capacity and $\lfloor \vartheta \rfloor$. However, since ϑ^- is not multiplicative, it is still not known whether there can be a gap between the *asymptotic* capacity (i.e. the entanglement assisted Shannon capacity) and ϑ . To show such a gap requires a stronger bound on entanglement assisted Shannon capacity. Haemers provided a bound on Shannon capacity which is sometimes stronger than Lovász' bound [23–26]; however, this bound does not apply to the entanglement assisted case [6].

The standard notion of graph homomorphism, along with two of its quantum generalizations, and our three relaxations, form a hierarchy as outlined in Fig. 3. In some cases we do not know whether converses hold. $G \xrightarrow{*} H$ is equivalent to $G \xrightarrow{q} H$ if and only if projective measurements and a maximally entangled state always suffice for entanglement assisted zero-error source-channel coding. Equivalence between $G \xrightarrow{*} H$ and $G \xrightarrow{\pm} H$ seems unlikely but would have two important consequences. First, we would have a much simpler characterization (vector rather than operator) of entanglement assisted homomorphisms and, in particular, entanglement assisted zero-error communication. Second, since $G \xrightarrow{V} H \implies G \xrightarrow{\pm} H$, the gap that we found between $G \xrightarrow{q} H$ and $G \xrightarrow{V} H$ would give a gap between $G \xrightarrow{q} H$ and $G \xrightarrow{*} H$.

Appendix A: Multiplicativity

In Lovász’ original paper [4] on the ϑ function, he proved that

$$\vartheta(G \boxtimes H) = \vartheta(G)\vartheta(H),$$

i.e. ϑ is multiplicative with respect to the strong product. To do this he proved the following two inequalities:

$$\vartheta(G)\vartheta(H) \leq \vartheta(G \boxtimes H) \leq \vartheta(G)\vartheta(H).$$

This sufficed for Lovász because it was only required to show that ϑ is multiplicative with respect to the strong product in order to prove that it was an upper bound on Shannon capacity. However, Lovász also

noted that his proof of the first inequality above also proves the following stronger statement:

$$\vartheta(G)\vartheta(H) \leq \vartheta(G * H).$$

Together these inequalities imply that ϑ is multiplicative with respect to both the strong and disjunctive products. Our aim in this appendix is to show that neither ϑ^- nor ϑ^+ are multiplicative with respect to both these products, but that ϑ^- is multiplicative with respect to the disjunctive product.

1. Counterexamples

Some of the inequalities involving ϑ above can be proved for ϑ^- as well. Adapting Lovász' proof of the analogous statement for ϑ , it can be shown that

$$\vartheta^-(G \boxtimes H) \geq \vartheta^-(G * H) \geq \vartheta^-(G)\vartheta^-(H).$$

Similarly, it can be shown that

$$\vartheta^+(G * H) \leq \vartheta^+(G \boxtimes H) \leq \vartheta^+(G)\vartheta^+(H).$$

Therefore, in order to show that neither ϑ^- or ϑ^+ are multiplicative with respect to both the strong and disjunctive products, we must find counterexamples to both of the following inequalities:

$$\vartheta^-(G \boxtimes H) \leq \vartheta^-(G)\vartheta^-(H), \quad \vartheta^+(G * H) \geq \vartheta^+(G)\vartheta^+(H).$$

At the end of [16], Schrijver gives an example of a graph, which we refer to as G_S , that satisfies $\vartheta^-(G_S) < \vartheta(G_S)$. The vertices of G_S are the 0-1-strings of length six, and two strings are adjacent if their Hamming distance is at most three. In other words, Schrijver's graph G_S is an instance of a *Hamming graph*. Note that this graph is vertex transitive. We will see how to use the graph G_S to construct counterexamples to both of the above inequalities. To do this we will need two lemmas, the first of which is from [4].

Lemma 19. *For any graph G ,*

$$\vartheta(G)\vartheta(\overline{G}) \geq |V(G)|,$$

with equality when G is vertex transitive.

An analogous statement involving ϑ^- and ϑ^+ was proved by Szegedy in [18]:

Lemma 20. *For any graph G ,*

$$\vartheta^-(G)\vartheta^+(\overline{G}) \geq |V(G)|,$$

with equality when G is vertex transitive.

One easy consequence of these lemmas is that if G is a vertex transitive graph such that $\vartheta^-(G) < \vartheta(G)$, then

$$\vartheta^+(\overline{G}) = \frac{|V(G)|}{\vartheta^-(G)} > \frac{|V(G)|}{\vartheta(G)} = \vartheta(\overline{G}).$$

In particular this implies that $\vartheta^+(\overline{G_S}) > \vartheta(\overline{G_S})$.

More pertinent to our discussion are the following lemmas.

Lemma 21. *If G is a vertex transitive graph such that $\vartheta^-(G) < \vartheta(G)$, then*

$$\vartheta^-(G \boxtimes \overline{G}) > \vartheta^-(G)\vartheta^-(\overline{G}).$$

Proof. First note the vertices of the form (v, v) in $G \boxtimes \overline{G}$ form an independent set of size $|V(G)|$. Therefore, $\vartheta^-(G \boxtimes \overline{G}) \geq |V(G)|$, and we have the following:

$$\vartheta^-(G)\vartheta^-(\overline{G}) < \vartheta(G)\vartheta(\overline{G}) = |V(G)| \leq \vartheta^-(G \boxtimes \overline{G}).$$

□

Since G_S satisfies the hypotheses of 21, we have the following desired corollary:

Corollary 22. *The parameter ϑ^- is not multiplicative with respect to the strong product.*

We are also able to use Lemma 21 to prove a similar lemma for ϑ^+ .

Lemma 23. *If G is a vertex transitive graph such that $\vartheta^-(G) < \vartheta(G)$, then*

$$\vartheta^+(G * \overline{G}) < \vartheta^+(G)\vartheta^+(\overline{G}).$$

Proof. Suppose that G is such a graph. By Lemma 21, we have that

$$\vartheta^-(G \boxtimes \overline{G}) > \vartheta^-(G)\vartheta^-(\overline{G}).$$

Since G is vertex transitive, so is $G * \overline{G}$ and thus we can apply Lemma 20 to obtain

$$\vartheta^+(G * \overline{G}) = \frac{|V(G)|^2}{\vartheta^-(G * \overline{G})} = \frac{|V(G)|^2}{\vartheta^-(G \boxtimes \overline{G})} < \frac{|V(G)|}{\vartheta^-(G)} \frac{|V(G)|}{\vartheta^-(\overline{G})} = \vartheta^+(G)\vartheta^+(\overline{G}).$$

□

Similarly to the above, this implies the following:

Corollary 24. *The parameter ϑ^+ is not multiplicative with respect to the disjunctive product.*

Even though ϑ^- is not multiplicative with respect to the strong product, nor is ϑ^+ with respect to the disjunctive product, one could ask whether they are at least multiplicative with respect to the corresponding graph powers, as this would be enough to prove an analogue of Corollary 9. It turns out that they are not, as we now show. Non-multiplicativity for ϑ^- was shown already in [27] but with a much smaller gap.

Corollary 25. *The parameter ϑ^- is not multiplicative under strong graph powers $G^{\boxtimes n}$, and ϑ^+ is not multiplicative under disjunctive graph powers G^{*n} .*

Proof. Let G_S be a vertex transitive graph such that $\vartheta^-(G_S) \leq \vartheta(G_S)$, whose existence was discussed above. Let $H = G_S \oplus \overline{G_S}$ where $\oplus$ denotes disjoint union. Since ϑ^- is additive under disjoint union and is super-multiplicative under the strong product,

$$\begin{aligned} \vartheta^-(H^{\boxtimes 2}) &= \vartheta^-[G_S^{\boxtimes 2} \oplus (G_S \boxtimes \overline{G_S}) \oplus (\overline{G_S} \boxtimes G_S) \oplus \overline{G_S}^{\boxtimes 2}] \\ &= \vartheta^-(G_S^{\boxtimes 2}) + \vartheta^-(G_S \boxtimes \overline{G_S}) + \vartheta^-(\overline{G_S} \boxtimes G_S) + \vartheta^-(\overline{G_S}^{\boxtimes 2}) \\ &\geq \vartheta^-(G_S)^2 + \vartheta^-(G_S \boxtimes \overline{G_S}) + \vartheta^-(\overline{G_S} \boxtimes G_S) + \vartheta^-(\overline{G_S})^2 \\ &> \vartheta^-(G_S)^2 + \vartheta^-(G_S)\vartheta^-(\overline{G_S}) + \vartheta^-(\overline{G_S})\vartheta^-(G_S) + \vartheta^-(\overline{G_S})^2 \\ &= [\vartheta^-(G_S) + \vartheta^-(\overline{G_S})]^2 \\ &= \vartheta^-(H)^2. \end{aligned}$$

Similarly,

$$\begin{aligned} \vartheta^+(H^{*2}) &= \vartheta^+[(G_S \oplus \overline{G_S}) * (G_S \oplus \overline{G_S})] \\ &\leq \vartheta^+[G_S^{\boxtimes 2} \oplus (G_S * \overline{G_S}) \oplus (\overline{G_S} * G_S) \oplus \overline{G_S}^{\boxtimes 2}] \\ &\leq \vartheta^+(G_S)^2 + \vartheta^+(G_S * \overline{G_S}) + \vartheta^+(\overline{G_S} * G_S) + \vartheta^+(\overline{G_S})^2 \\ &< \vartheta^+(G_S)^2 + \vartheta^+(G_S)\vartheta^+(\overline{G_S}) + \vartheta^+(\overline{G_S})\vartheta^+(G_S) + \vartheta^+(\overline{G_S})^2 \\ &= [\vartheta^+(G_S) + \vartheta^+(\overline{G_S})]^2 \\ &= \vartheta^+(H)^2. \end{aligned} \tag{A1}$$

where (A1) follows from the fact that $\vartheta^+(G_1) \geq \vartheta^+(G_2)$ when G_1 is a subgraph of G_2 . □

2. ϑ^- and the Strong Product

Though ϑ^- is not multiplicative with respect to the strong product, we are able to show that it is multiplicative with respect to the disjunctive product. We have already noted above that

$$\vartheta^-(G * H) \geq \vartheta^-(G)\vartheta^-(H).$$

Therefore it is only left to show that

$$\vartheta^-(G * H) \leq \vartheta^-(G)\vartheta^-(H)$$

for all graphs G and H . To do this we will use the following formulation of ϑ^- :

$$\begin{aligned} \vartheta^-(G) = \min \quad & \|M\| \\ \text{s.t.} \quad & M_{uu'} \geq 1 \text{ if } u \not\sim u' \\ & M \text{ is symmetric} \end{aligned}$$

Using this definition of ϑ^- , we are able to prove the following:

Theorem 26. *For any graphs G and H ,*

$$\vartheta^-(G * H) = \vartheta^-(G)\vartheta^-(H).$$

Proof. As mentioned, we only need to show that $\vartheta^-(G * H) \leq \vartheta^-(G)\vartheta^-(H)$. Suppose that matrices A and B are optimal solutions to this formulation of ϑ^- for graphs G and H respectively. We claim that $A \otimes B$ is a solution to the above formulation of ϑ^- for the graph $G * H$ of value $\vartheta^-(G)\vartheta^-(H)$.

Obviously, $A \otimes B$ is symmetric. Since the eigenvalues of a tensor product are the products of the eigenvalues of its factors, we have that

$$\|A \otimes B\| = \|A\| \cdot \|B\| = \vartheta^-(G)\vartheta^-(H).$$

Note that “ $(u, v) \not\sim (u', v')$ ” is equivalent to “ $u \not\sim u'$ and $v \not\sim v'$ ”. Since $(A \otimes B)_{(u,v)(u',v')} = A_{uu'}B_{vv'}$, this implies that if $(u, v) \not\sim (u', v')$ in $G * H$, then $(A \otimes B)_{(u,v)(u',v')} \geq 1$. Therefore $\vartheta^-(G * H) \leq \vartheta^-(G)\vartheta^-(H)$. $\square$

3. What About ϑ^+ ?

Based on other results concerning ϑ^- and ϑ^+ , Theorem 26 seems to suggest that one should be able to prove that ϑ^+ is multiplicative with respect to the strong product. We already noted above that one of the needed inequalities, namely $\vartheta^+(G \boxtimes H) \leq \vartheta^+(G)\vartheta^+(H)$, does hold, so we would only need to show that $\vartheta^+(G \boxtimes H) \geq \vartheta^+(G)\vartheta^+(H)$ holds as well. For now, a proof of this fact alludes us, but we are able to prove the multiplicativity of ϑ^+ in the case of vertex transitive graphs using Lemma 20 and the multiplicativity of ϑ^- with respect to the disjunctive product.

Theorem 27. *If G and H are vertex transitive, then*

$$\vartheta^+(G \boxtimes H) = \vartheta^+(G)\vartheta^+(H).$$

Proof. Since G and H are vertex transitive, so is $G \boxtimes H$. Therefore

$$\vartheta^+(G \boxtimes H) = \frac{|V(G)| \cdot |V(H)|}{\vartheta^-(G * H)} = \frac{|V(G)| \cdot |V(H)|}{\vartheta^-(G)\vartheta^-(H)} = \vartheta^+(G)\vartheta^+(H).$$

$\square$

This seems to be pretty strong evidence that ϑ^+ is multiplicative with respect to the strong product in general.

Appendix B: An if-and-only-if for Schrijver's number

Monotonicity of Schrijver's number admits an if-and-only-if statement along the lines of Theorem 6; however, the corresponding conditions on the $|w_s^x\rangle$ vectors are a bit more complicated and there is seemingly no direct connection to entanglement assisted source-channel coding. Specifically, we have the following result:

Theorem 28. $\bar{\vartheta}^-(G) \leq \bar{\vartheta}^-(H)$ if and only if there are vectors $|w\rangle \neq 0$ and $|w_s^x\rangle \in \mathbb{C}^d$ for each $x \in V(G)$, $s \in V(H)$, for some $d \in \mathbb{N}$, such that

1. $\sum_s |w_s^x\rangle = |w\rangle$
2. $\langle w_s^x | w_t^y \rangle = 0$ for $s \not\sim_H t$, $s \neq t$
3. $\langle w_s^x | w_s^y \rangle \leq 0$ for $x \sim_G y$
4. $\langle w_s^x | w_t^x \rangle = 0$ for $s \neq t$
5. $\langle w_s^x | w_t^y \rangle \geq 0$ for $s \neq t$.

The proof is a straightforward modification of the proof for Theorem 6. Before proceeding with this, it is necessary to express $\bar{\vartheta}^-$ in a form analogous to (10). We do not know how to provide such a formulation for $\bar{\vartheta}^+$, so it may be possible that $\bar{\vartheta}^+$ does not admit an if-and-only-if statement along the lines of Theorems 6 and 28.

Theorem 29.

$$\begin{aligned} \bar{\vartheta}^-(G) = \max\{ & \|I + T\| : I + T \succeq 0, \\ & T_{ij} = 0 \text{ for } i \not\sim j, \\ & T_{ij} \geq 0 \text{ for all } i, j\}. \end{aligned} \quad (\text{B1})$$

Proof. The dual to the semidefinite program (12) is [16]

$$\begin{aligned} \bar{\vartheta}^-(G) = \max\{ & \langle B, J \rangle : B \succeq 0, \\ & \text{Tr} B = 1, \\ & B_{ij} = 0 \text{ for } i \not\sim j, i \neq j, \\ & B_{ij} \geq 0 \text{ for all } i, j\}. \end{aligned} \quad (\text{B2})$$

Let T be the optimal solution for (B1). We will show that this induces a feasible solution for (B2) via the recipe

$$B = |\psi\rangle \langle \psi| \circ (I + T),$$

where $|\psi\rangle$ is the eigenvector corresponding to the largest eigenvalue of $I + T$. This is positive semidefinite (being the Schur-Hadamard product of two positive semidefinite matrices), and $\langle B, J \rangle = \langle \psi | I + T | \psi \rangle = \lambda$. T_{ii} vanishes, so the diagonal of B is equal to the diagonal of $|\psi\rangle \langle \psi|$; consequently $\text{Tr} B = 1$. The matrix $I + T$ has nonnegative entries so its eigenvector $|\psi\rangle$ can be chosen nonnegative, leading to $B_{ij} \geq 0$. So B is feasible for (B2) and (B2) $\geq$ (B1).

Conversely, suppose that B is feasible for (B2) with value λ . Let D be the diagonal component of B . Let $D^{-1/2}$ be the diagonal matrix having entries $D_{ii}^{-1/2} = 1/\sqrt{B_{ii}}$ with the convention $1/0 = 0$ (note that $D^{-1/2}$ is the Moore-Penrose pseudoinverse of $D^{1/2}$). Define

$$T = D^{-1/2}(B - D)D^{-1/2}.$$

When $i \not\sim j$, this matrix satisfies $T_{ij} = 0$. Since D and $B - D$ have nonnegative entries, T does as well. We have

$$\begin{aligned} I + T & \succeq D^{-1/2} D D^{-1/2} + T \\ & = D^{-1/2} B D^{-1/2} \\ & \succeq 0. \end{aligned} \quad (\text{B3})$$

So T is feasible for (B1). Let $|\psi\rangle$ be the vector with coefficients $\psi_i = \sqrt{B_{ii}}$. Making use of (B3),

$$\begin{aligned}
\langle \psi | I + T | \psi \rangle &\geq \left\langle \psi \left| D^{-1/2} B D^{-1/2} \right| \psi \right\rangle \\
&= \sum_{\substack{ij \text{ s.t.} \\ B_{ii} B_{jj} \neq 0}} B_{ij} \\
&= \sum_{ij} B_{ij} \\
&= \langle J, B \rangle = \lambda.
\end{aligned} \tag{B4}$$

Equality (B4) holds because B is positive semidefinite and so satisfies $B_{ij} = 0$ when $B_{ii} B_{jj} = 0$. Since T is feasible for (B1),

$$(B1) \geq \|I + T\| \geq \lambda = (B2).$$

□

Proof of Theorem 28. As in the proof of Theorem 6, we work with the Gram matrix of the $|w_s^x\rangle$ vectors. The existence of vectors satisfying the conditions in the theorem statement is easily seen to be equivalent to the existence of a matrix $C : \mathcal{L}(\mathbb{C}^{|V(G)|}) \otimes \mathcal{L}(\mathbb{C}^{|V(H)|})$ satisfying

$$\begin{aligned}
C &\succeq 0 \\
\sum_{st} C_{xyst} &= 1 \\
C_{xyst} &= 0 \text{ for } s \not\sim t, s \neq t \\
C_{xyss} &\leq 0 \text{ for } x \sim y \\
C_{xxst} &= 0 \text{ for } s \neq t \\
C_{xyst} &\geq 0 \text{ for } s \neq t
\end{aligned}$$

Using this characterization, we proceed with the proof.

($\implies$): Suppose $\bar{\vartheta}^-(G) \leq \bar{\vartheta}^-(H)$. We will explicitly construct a matrix C having the above properties. Let $\lambda = \bar{\vartheta}^-(H)$. By Theorem 29 there is a matrix T such that $\|I + T\| = \lambda$, $I + T \succeq 0$, $T_{st} = 0$ for $s \not\sim t$, and $T_{st} \geq 0$ for all s, t . Let $|\psi\rangle$ be the vector corresponding to the largest eigenvalue of $I + T$, which can be chosen nonnegative since T is entrywise nonnegative. With $\circ$ denoting the Schur-Hadamard product, define the matrices

$$\begin{aligned}
D &= |\psi\rangle \langle \psi| \circ I, \\
B &= |\psi\rangle \langle \psi| \circ (I + T).
\end{aligned}$$

These are entrywise nonnegative. With J being the all-ones matrix and $\langle \cdot, \cdot \rangle$ denoting the Hilbert-Schmidt inner product, it is readily verified that

$$\begin{aligned}
\langle D, J \rangle &= \langle \psi | \psi \rangle = 1, \\
\langle B, J \rangle &= \langle \psi | I + T | \psi \rangle = \lambda.
\end{aligned}$$

Schur-Hadamard products between positive semidefinite matrices yield positive semidefinite matrices. As a consequence, $B \succeq 0$ and

$$\|I + T\| = \lambda \implies \lambda I - (I + T) \succeq 0 \implies \lambda D - B \succeq 0.$$

Since $\lambda \geq \bar{\vartheta}^-(G)$, there is a matrix Z such that $Z \succeq 0$, $Z_{xx} = \lambda - 1$ for all x , and $Z_{xy} \leq -1$ for all $x \sim y$. Note that (12) gives existence of a matrix with $\bar{\vartheta}^-(G) - 1$ on the diagonal, but since $\lambda \geq \bar{\vartheta}^-(G)$ we can add a multiple of the identity to get $\lambda - 1$ on the diagonal.

We now construct C . Define

$$C = \lambda^{-1} [J \otimes B + (\lambda - 1)^{-1} Z \otimes (\lambda D - B)].$$

Since J , B , Z , and $\lambda D - B$ are all positive semidefinite, and $\lambda - 1 \geq 0$, we have that C is positive semidefinite. The other desired conditions on C are easy to verify. For all x, y we have

$$\begin{aligned} \sum_{st} C_{xyst} &= \lambda^{-1} [J_{xy} \langle B, J \rangle + (\lambda - 1)^{-1} Z_{xy} [\lambda \langle D, J \rangle - \langle B, J \rangle]] \\ &= J_{xy} = 1. \end{aligned}$$

For $s \not\sim t$, $s \neq t$, we have that $B_{st} = D_{st} = 0$ so $C_{xyst} = 0$. For $x \sim y$,

$$\begin{aligned} C_{xyss} &= \lambda^{-1} [B_{ss} + (\lambda - 1)^{-1} Z_{xy} (\lambda D_{ss} - B_{ss})] \\ &= \lambda^{-1} [D_{ss} + (\lambda - 1)^{-1} Z_{xy} (\lambda D_{ss} - D_{ss})] \\ &= \lambda^{-1} D_{ss} [1 + Z_{xy}] \\ &\leq 0. \end{aligned}$$

For all x and for $s \neq t$,

$$\begin{aligned} C_{xxst} &= \lambda^{-1} [B_{st} + (\lambda - 1)^{-1} Z_{xx} (\lambda D_{st} - B_{st})] \\ &= \lambda^{-1} B_{st} [1 - (\lambda - 1)^{-1} Z_{xx}] \\ &= 0. \end{aligned}$$

For all x, y and for $s \neq t$,

$$\begin{aligned} C_{xyst} &= \lambda^{-1} [B_{st} + (\lambda - 1)^{-1} Z_{xy} (\lambda D_{st} - B_{st})] \\ &= \lambda^{-1} B_{st} [1 - (\lambda - 1)^{-1} Z_{xy}] \\ &\geq 0, \end{aligned}$$

where the last inequality follows from the fact that $Z \succeq 0 \implies |Z_{xy}| \leq Z_{xx} = \lambda - 1$.

($\Leftarrow$): Let Z achieve the optimal value (call it λ) for the minimization program (12) for $\bar{\vartheta}^-(H)$. We will provide a feasible solution for (12) for $\bar{\vartheta}^-(G)$ to show that $\bar{\vartheta}^-(G) \leq \bar{\vartheta}^-(H)$. Specifically, let $Y_{xy} = \sum_{st} Z_{st} C_{xyst}$. $C \succeq 0$ and $Z \succeq 0$, so by Choi's theorem on completely positive maps $Y \succeq 0$.

Using the fact that $Z_{ss} = \lambda - 1$ and $C_{xxst} = 0$ for $s \neq t$, we have

$$Y_{xx} = \sum_{st} Z_{st} C_{xxst} = (\lambda - 1) \sum_{st} C_{xxst} = \lambda - 1.$$

For $x \sim y$ we have

$$\begin{aligned} Y_{xy} &= \sum_{st} Z_{st} C_{xyst} \\ &= \sum_{s \sim t} \underbrace{Z_{st}}_{\leq -1} \underbrace{C_{xyst}}_{\geq 0} + \sum_{s \not\sim t, s \neq t} \underbrace{Z_{st}}_{=0} C_{xyst} + \sum_s \underbrace{Z_{ss}}_{\geq -1} \underbrace{C_{xyss}}_{\leq 0} \\ &\leq \sum_{s \sim t} (-1) C_{xyst} + \sum_{s \not\sim t, s \neq t} (-1) C_{xyst} + \sum_s (-1) C_{xyss} \\ &= \sum_{st} (-1) C_{xyst} = -1. \end{aligned}$$

Now define a matrix Y' consisting of the real part of Y (i.e. with coefficients $Y'_{xy} = \text{Re}[Y_{xy}]$). This matrix is real, positive semidefinite, and satisfies $Y'_{xx} = \lambda - 1$ for all x and $Y'_{xy} \leq -1$ for $x \sim y$. Therefore Y' is feasible for (12) with value $\lambda = \bar{\vartheta}^-(H)$. Since $\bar{\vartheta}^-(G)$ is the minimum possible value of (12), we have $\bar{\vartheta}^-(G) \leq \bar{\vartheta}^-(H)$. $\square$

By setting $G = K_n$ or $H = K_n$ it is possible to formulate corollaries analogous to Corollaries 7 and 8. We describe only the first of these here.

Corollary 30. *Let $\beta^-(H)$ be the largest n such that there are vectors $|w\rangle \neq 0$ and $|w_s^x\rangle \in \mathbb{C}^d$ for each $x \in \{1, \dots, n\}$, $s \in V(H)$, for some $d \in \mathbb{N}$, such that*

1. $\sum_s |w_s^x\rangle = |w\rangle$
2. $\langle w_s^x | w_t^y \rangle = 0$ for $s \sim_H t$
3. $\langle w_s^x | w_s^y \rangle \leq 0$ for $x \neq y$
4. $\langle w_s^x | w_t^x \rangle = 0$ for $s \neq t$
5. $\langle w_s^x | w_t^y \rangle \geq 0$ for $s \neq t$.

Then $\beta^-(H) = \lfloor \vartheta^-(H) \rfloor$.
