(Received 6 November 2017; published 16 April 2018)

The mass loss of an isolated gravitating system due to energy carried away by gravitational waves with a cosmological constant $\Lambda \in \mathbb{R}$ was recently worked out, using the Newman-Penrose-Unti approach. In that same article, an expression for the Bondi mass of the isolated system, M_Λ , for the $\Lambda > 0$ case was proposed. The stipulated mass M_Λ would ensure that in the absence of any incoming gravitational radiation from elsewhere the emitted gravitational waves must carry away a positive-definite energy. That suggested quantity, however, introduced a Λ -correction term to the Bondi mass M_B (where M_B is the usual Bondi mass for asymptotically flat spacetimes), which would involve information not just on the state of the system at that moment but ostensibly also its past history. In this paper, we derive the identical mass-loss equation using an integral formula on a hypersurface formulated by Frauendiener based on the Nester-Witten identity and argue that one may adopt a generalization of the Bondi mass with $\Lambda \in \mathbb{R}$ *without any correction*, viz., $M_\Lambda = M_B$ for any $\Lambda \in \mathbb{R}$. Furthermore, with $M_\Lambda = M_B$, we show that for *purely quadrupole gravitational waves* given off by the isolated system (i.e., when the “Bondi news” σ^o comprises only the $l = 2$ components of the spherical harmonics with spin-weight 2) the energy carried away is *manifestly positive definite* for the $\Lambda > 0$ case. For a general σ^o having higher multipole moments, this perspicuous property in the $\Lambda > 0$ case still holds if those $l > 2$ contributions are weak—more precisely, if they satisfy any of the inequalities given in this paper.

I. INTRODUCTION

The past couple of years have indubitably been a fascinating time to be working on gravitational physics. Since the inaugural direct detection of gravitational waves originating from a binary black hole system was announced in February 2016 (one century after Albert Einstein formulated his theory of general relativity in November 1915) [1], several more such detections have been announced [2–5]. Intriguingly, the most recent ones are not just signals picked up by LIGO’s twin detectors but also by VIRGO [4,5] as well as other nongravitational detections, including those coming from a binary neutron star system [5]. It is certainly apt that this year’s (2017, when this manuscript was written) Nobel Prize in Physics goes to the scientists who represent the global collaboration to make direct observations of gravitational waves a reality, opening up exciting new territories for learning about our Universe.

While it was considerably long before the experimentalists’ breakthrough occurred, the amount of time taken to concretely build the *theoretical foundation* for gravitational waves was of a comparable order of magnitude, when it was only firmly established by Bondi and his coworkers in the 1960s [6,7]. Since then, we have better understood the

global and asymptotic structure of spacetime. In particular, for an isolated system such that spacetime is asymptotically empty, there exist asymptotic symmetries, and these asymptotic symmetries can be used in a Hamiltonian framework to obtain the Bondi mass [8–10]—in agreement with Bondi’s original proposal. There was an underlying assumption in the vast majority of the work back then, however, that spacetime is *asymptotically flat* [11].

If we look back at the preceding Nobel Prize in Physics being awarded to the field of gravitation and cosmology, that was in 2011 for the discovery of the accelerated expansion of our Universe. That revelation meant that one cannot assume that the cosmological constant Λ in Einstein’s theory of general relativity is zero, without introducing extra properties to spacetime. A way to account for this phenomenon is to simply admit $\Lambda > 0$ into Einstein’s theory. In fact, there have been investigations taking place over the past few years by many researchers employing a raft of methods to extend the notion of the Bondi mass and the energy carried by gravitational waves to include a positive cosmological constant. (See, for instance, Ref. [14] for a review on the progress thitherto and the references therein.)

One approach to include a cosmological constant with any sign or value, i.e., $\Lambda \in \mathbb{R}$, is to use the Newman-Penrose formalism [15–17] [18], as Newman and Unti also

^{*}Vee-Liem Saw@ntu.edu.sg

obtained the same mass-loss formula for an isolated gravitating system due to energy carried away by gravitational waves for $\Lambda = 0$ [20] (during the same period when Bondi reported his results). The corresponding mass-loss formula with $\Lambda \in \mathbb{R}$ was derived in Ref. [15] using this Newman-Penrose-Unti approach, with a proposal for the Bondi mass in a universe with $\Lambda > 0$ being [21]

$$M_\Lambda := M_B + \frac{\Lambda}{3A} \int \left(\oint K |\sigma^o|^2 d^2 S \right) du, \quad (1)$$

where $M_B = -A^{-1} \oint (\Psi_2^o + \sigma^o \bar{\sigma}^o) d^2 S$ is the Bondi mass in an asymptotically flat universe and $A = 4\pi$ is the area of a round unit 2-sphere. In the above expression, Ψ_2^o is the leading-order term of the dyad component of the Weyl spinor Ψ_2 when expanded in inverse powers of r away from null infinity $\mathcal{I}$, and σ^o is the leading-order term for the spin coefficient σ . The symbol K is the Gauss curvature for the topological 2-spheres of constant u on $\mathcal{I}$. With $\Lambda \neq 0$, we would have $\mathcal{I}$ being nonconformally flat when $\sigma^o \neq 0$, and consequently K is not 1 but is instead 1 plus terms involving σ^o with an overall factor of Λ [Eq. (25)] [22]. The correction term to the Bondi mass M_B from the asymptotically flat case to get M_Λ for the $\Lambda > 0$ case was proposed as in Eq. (1) in order to guarantee that the resulting mass-loss formula,

$$\begin{aligned} \frac{dM_\Lambda}{du} = & -\frac{1}{A} \oint \left(|\dot{\sigma}^o|^2 + \frac{\Lambda}{3} |\delta' \sigma^o|^2 \right. \\ & \left. + \frac{2\Lambda^2}{9} |\sigma^o|^4 + \frac{\Lambda^2}{18} \text{Re}(\bar{\sigma}^o \Psi_0^o) \right) d^2 S, \end{aligned} \quad (2)$$

is manifestly positive definite with an overall negative sign when Ψ_0^o (the leading-order term of Ψ_0 which represents incoming radiation from elsewhere) is zero, so that the gravitational waves emitted by the isolated system carry away a positive-definite energy and reduce the mass M_Λ . This mass-loss formula arises from the same Bianchi identity that Newman and Unti obtained for the asymptotically flat case, i.e., the one involving $D'\Psi_2$ —which, incidentally, corresponds to the “supplementary condition” upon which Bondi got the mass-loss formula [6].

Around the same time this work in Ref. [15] was being carried out, a Bondi-type mass with Λ was independently given by Chruściel and Ifsits [23], containing a correction term to which they referred as a “renormalized volume of the null hypersurface” (with alternative ways of reexpressing and redefining terms, as well as possibly moving the terms across the $=$ sign, in their “balance formula”). Although we presently do not know how to directly relate these two proposals of the Bondi mass with $\Lambda > 0$ in Refs. [15,23] (as the notations and conventions used in these papers are disparate), it seemed plausible (and natural) to have a generalization of M_B to the $\Lambda > 0$ case with new terms involving Λ [24]. The correction term in Eq. (1) proposed in Ref. [15] may also be interpreted as a

volume integral since it involves an integral over a 2-surface of constant u on $\mathcal{I}$ with a further integration over u on $\mathcal{I}$. A research direction would then be to reconcile these two approaches and validate the connection between these two “volume correction terms.”

However, the nature of an integral over u (in an expression describing the mass of an isolated system at some particular moment $u = u_0$) implies that one would allegedly require information of the system not just at that moment but also of its past history from, say, $u = 0$, upon where that integral is carried out from—unless one is able to express that volume integral entirely in terms of local expressions at $u = u_0$. The presence of such a volume integral would be perceived as a significant departure from the asymptotically flat case. Unfortunately, one faces formidable (but hopefully not irreconcilable) difficulty in attempting to pin down an exact notion of the Bondi mass when $\Lambda \neq 0$, because this Λ destroys the asymptotic symmetries which formed the concrete basis for a Hamiltonian treatment of the Bondi mass when $\Lambda = 0$ [14]. A ramification of this is the ambiguity in definitively defining the Bondi mass, as demonstrated by the undesirable freedom for moving terms around in Eq. (2) to be absorbed into the definition of M_Λ , or even adding conceivably arbitrary terms on both sides.

Ergo, the goal of this paper is to provide a way to not only obtain the mass-loss formula but also argue for a reasonable generalization of the Bondi mass with $\Lambda > 0$ [25]. We will do this by applying an integral formula on a hypersurface that was found by Frauendiener, using the Nester-Witten identity [26]. The idea would be to apply the asymptotic expansions for the spin coefficients with $\Lambda \in \mathbb{R}$ that were recently worked out in Ref. [15] and plug them into the integral formula. This was one of the applications illustrated by Frauendiener, viz., to produce the Bondi mass-loss formula for the asymptotically flat case. The Nester-Witten identity may be expressed in the form $dL = S + E$, and it is this geometric object dL (a 3-form) that involves a differential of L (a 2-form) that becomes the expression for the rate of change of the Bondi mass M_B . We adopt the exact steps and find that with $\Lambda \in \mathbb{R}$ this geometric object dL turns out to be *precisely the same expression*, dM_B/du . Incidentally, we find that the integral formula yields the identical mass-loss formula with $\Lambda \in \mathbb{R}$ that was first reported in Ref. [15], as anticipated.

In the next section, we present the pair of integral formulas on a hypersurface from Ref. [26] and express them in a form that would be true for any $\Lambda \in \mathbb{R}$. With this, we can derive the expected mass-loss formula with $\Lambda \in \mathbb{R}$ in Sec. III. To do so, a number of technical steps are required, which are organized into four subsections. With a generalization of the Bondi mass to include $\Lambda \in \mathbb{R}$ being just $M_\Lambda = M_B$ (as this is the expression appearing in the geometric object dL for any $\Lambda \in \mathbb{R}$), the sole term that is not *manifestly* positive definite (in the absence of incoming

radiation from elsewhere) for the $\Lambda > 0$ case involves the Gauss curvature K of the topological 2-spheres of constant u on $\mathcal{I}$. We show in Sec. IV that we can express this in terms of $\delta'\sigma^o$ and $\delta\sigma^o$, using an identity for the commutator of the δ and δ' operators [27]. With this, we see that if σ^o (which is a spin-weighted quantity with spin weight $s = 2$ [27,28]) only has $l = 2$ components (which represent the quadrupole terms in a multipole expansion of the compact isolated source) then the mass loss for $M_\Lambda = M_B$ in the $\Lambda > 0$ case is manifestly positive definite, viz., quadrupole gravitational waves carry away positive-definite energy. Several inequalities are given, which would guarantee this manifestly positive-definite property for a general σ^o , in a universe with $\Lambda > 0$.

To recapitulate the behavior of empty asymptotically de Sitter spacetimes, we briefly summarize the main points from Ref. [15] in Appendix A. There, we state the assumptions used to derive these asymptotic solutions, as well as what free functions are left in order to specify a unique solution. The stipulations on the falloffs for the spin coefficients and unknown functions in the null tetrad used in Ref. [15], together with the vanishing of the Weyl spinor on $\mathcal{I}$ (i.e., without having to additionally assume that $\Psi_0 = \Psi_0^o r^{-5} + O(r^{-6})$ [29]) are consistent with assuming a smooth conformal compactifiability; this can be clearly seen by an application of a boost transformation of the $\vec{l}$ and $\vec{n}$ null vectors (this boost transformation was discussed explicitly in Ref. [16], in which the asymptotic solutions were expressed in a Szabados-Tod-type null tetrad), together with a null rotation about $\vec{l}$ to arrive at the results reported by Szabados and Tod [30]. (This null rotation gets rid of ω so that $\vec{m}$ and $\vec{\bar{m}}$ do not have a $\vec{\partial}_r$ component. Incidentally, such a null rotation is carried out in Sec. III A because the integral formulas by Frauendiener assumed such $\vec{m}$ and $\vec{\bar{m}}$.) Lastly, we give in Appendix B a proof that the area element of the topological 2-sphere of constant u on $\mathcal{I}$, denoted by d^2S , is independent of u . This implies that the term involving $\partial(d^2S)/\partial u$ in the proposal for M_Λ in Ref. [15] [see Eq. (126) in that paper] is zero.

II. INTEGRAL FORMULAS ON A HYPERSURFACE, ARISING FROM THE NESTER-WITTEN IDENTITY

Frauendiener derived a pair of integral formulas on some hypersurface Σ based on the Nester-Witten identity of the form $dL = S + E$ [26,31]:

$$\begin{aligned} \frac{d}{ds} \oint \rho \phi d^2A &= \oint \rho \frac{d\phi}{ds} d^2A + \oint Z\phi(\sigma\bar{\sigma} - \rho^2) d^2A \\ &+ \oint Z'\phi\left(\frac{\mathcal{R}}{4} - \tau\bar{\tau}\right) d^2A \\ &- \frac{1}{2} \oint \phi l^a G_a{}^b p_{bc} Z^c d^2A, \quad \text{and} \end{aligned} \quad (3)$$

$$\begin{aligned} \frac{d}{ds} \oint \rho' \phi' d^2A &= \oint \rho' \frac{d\phi'}{ds} d^2A + \oint Z'\phi'(\sigma'\bar{\sigma}' - \rho'^2) d^2A \\ &+ \oint Z\phi'\left(\frac{\mathcal{R}}{4} - \tau'\bar{\tau}'\right) d^2A \\ &+ \frac{1}{2} \oint \phi' n^a G_a{}^b p_{bc} Z^c d^2A. \end{aligned} \quad (4)$$

The left-hand sides are dL , with E being the term involving the Einstein tensor $G_a{}^b$ on the right-hand sides, and the rest of the terms on the right-hand sides are S . The greek letters $\rho, \rho', \sigma, \sigma', \tau$, and τ' that appear in these formulas are the usual spin coefficients of the Newman-Penrose formalism. The notations and conventions used by Frauendiener are (probably almost) consistent with those in Penrose-Rindler [27,32] [33] for the case with zero cosmological constant and with Refs. [15,16] for the case with a cosmological constant $\Lambda \in \mathbb{R}$ (apart from the null tetrad, but this can be reconciled via a null rotation around $\vec{l}$ —see Sec. III A).

In the setup by Frauendiener, the three-dimensional hypersurface Σ under consideration is assumed to be foliated by a set of topological 2-spheres S_s (each value of s labels one such surface), with $\mathcal{R}$ being the scalar curvature of S_s [34]. The surface integral is carried out over S_s , for some fixed s , and its area element is $d^2A = m_{ab}$. An outgoing unit normal to these topological 2-spheres is denoted by $\hat{Z}$ (but one can certainly consider any arbitrary length $\vec{Z}$ parallel to $\hat{Z}$ —in particular, if $\vec{Z}$ is null, then it always has zero length), which may be decomposed into $\vec{Z} = Z\vec{l} + Z'\vec{n}$, and the s derivative is a directional derivative along $\vec{Z}$. We have here $\{\vec{l}, \vec{n}, \vec{m}, \vec{\bar{m}}\}$ forming a null tetrad (the first two are orthogonal to S_s , while the latter two are tangent to S_s), with the induced area elements given by $p_{ab} = l_a n_b - n_a l_b$ and $m_{ab} = -i(m_a \bar{m}_b - \bar{m}_a m_b)$. The functions ϕ and ϕ' are types $(-1, -1)$ and $(1, 1)$ functions [27] on Σ . While these functions are left in there in Ref. [26], they should just correspond to a boost transformation of the $\vec{l}$ and $\vec{n}$ null vectors. In other words, one can just set ϕ and ϕ' to 1 (but we will, for the moment, leave these ϕ and ϕ' in there).

To deal with the case with a cosmological constant $\Lambda \in \mathbb{R}$, we need a few things here and to reexpress these integral formulas. First, Frauendiener assumed that the spin coefficients γ and γ' vanish on Σ , as he imposed that the spinor dyads o^A and ι^A obey the propagations $Do^A = 0$ and $D'\iota^A = 0$. Such conditions, however, cannot be satisfied when there is $\Lambda \in \mathbb{R}$ (in particular, it was found in Ref. [15] that $\gamma = O(r)$ due to Λ), and so these terms involving γ and γ' must be restored into the integral formulas, viz.,

$$\oint 2\rho\phi(Z'\text{Re}(\gamma) - Z\text{Re}(\gamma')) d^2A \text{ into Eq. (3) and } (5)$$

$$\oint 2\rho'\phi'(Z\text{Re}(\gamma') - Z'\text{Re}(\gamma)) d^2A \text{ into Eq. (4). } (6)$$

Apart from that, the Einstein tensor is not zero but is given by the Einstein field equations as $G_a^b = -\Lambda \delta_a^b$. With this as well as $p_{bc} = l_b n_c - n_b l_c$, $Z^c = Z l^c + Z' n^c$, and the orthonormalization of $\vec{l}$ and $\vec{n}$ ($l^a n_a = 1$ and $l^a l_a = n^a n_a = 0$), the last term in Eq. (3) becomes

$$-\frac{1}{2} \oint \phi l^a G_a^b p_{bc} Z^c d^2 A = \frac{1}{2} \oint \Lambda \phi l^a \delta_a^b (l_b n_c - n_b l_c) (Z l^c + Z' n^c) d^2 A \quad (7)$$

$$= \frac{1}{2} \oint \Lambda \phi l^b (Z l_b - Z' n_b) d^2 A \quad (8)$$

$$= -\frac{1}{2} \oint Z' \Lambda \phi d^2 A. \quad (9)$$

Similarly, the last term in Eq. (4) becomes

$$\frac{1}{2} \oint \phi' n^a G_a^b p_{bc} Z^c d^2 A = -\frac{1}{2} \oint Z \Lambda \phi' d^2 A. \quad (10)$$

With these to account for $\Lambda \in \mathbb{R}$ (as far as we are able to detect), the pair of integral formulas from Eqs. (3) and (4) is

$$\begin{aligned} \frac{d}{ds} \oint \rho \phi d^2 A &= \oint \rho \frac{d\phi}{ds} d^2 A + \oint \rho \phi (2Z' \text{Re}(\gamma) \\ &\quad - Z(2\text{Re}(\gamma') + \rho)) d^2 A + \oint Z \phi \sigma \bar{\sigma} d^2 A \\ &\quad + \oint Z' \phi \left(\frac{\mathcal{R}}{4} - \frac{\Lambda}{2} - \tau \bar{\tau} \right) d^2 A, \quad \text{and} \quad (11) \end{aligned}$$

$$\begin{aligned} \frac{d}{ds} \oint \rho' \phi' d^2 A &= \oint \rho' \frac{d\phi'}{ds} d^2 A + \oint \rho' \phi' (2Z \text{Re}(\gamma') \\ &\quad - Z'(2\text{Re}(\gamma) + \rho')) d^2 A + \oint Z' \phi' \sigma' \bar{\sigma}' d^2 A \\ &\quad + \oint Z \phi' \left(\frac{\mathcal{R}}{4} - \frac{\Lambda}{2} - \tau' \bar{\tau}' \right) d^2 A. \quad (12) \end{aligned}$$

Incidentally, the left-hand side of Eq. (11) (which is the dL of the Nester-Witten identity $dL = S + E$) can be expanded as

$$\begin{aligned} \frac{d}{ds} \oint \rho \phi d^2 A &= \oint \frac{d}{ds} (\rho \phi d^2 A) \\ &= \oint \left(\frac{d\rho}{ds} \phi d^2 A + \rho \phi \frac{d(d^2 A)}{ds} + \rho \frac{d\phi}{ds} d^2 A \right), \quad (13) \end{aligned}$$

so we find that the term involving the s derivative of ϕ exactly cancels out the corresponding term on the right-hand side. The remaining terms all involve a factor of ϕ , and since ϕ is an arbitrary function, we must have the

following integral formulas [where similar remarks hold for Eq. (12)] independent of ϕ (and ϕ')—or just set ϕ and ϕ' to 1 [35]:

$$\begin{aligned} \oint \frac{d\rho}{ds} d^2 A + \oint \rho \frac{d(d^2 A)}{ds} \\ &= \oint \rho (2Z' \text{Re}(\gamma) - Z(2\text{Re}(\gamma') + \rho)) d^2 A + \oint Z \sigma \bar{\sigma} d^2 A \\ &\quad + \oint Z' \left(\frac{\mathcal{R}}{4} - \frac{\Lambda}{2} - \tau \bar{\tau} \right) d^2 A, \quad \text{and} \quad (14) \end{aligned}$$

$$\begin{aligned} \oint \frac{d\rho'}{ds} d^2 A + \oint \rho' \frac{d(d^2 A)}{ds} \\ &= \oint \rho' (2Z \text{Re}(\gamma') - Z'(2\text{Re}(\gamma) + \rho')) d^2 A \\ &\quad + \oint Z' \sigma' \bar{\sigma}' d^2 A + \oint Z \left(\frac{\mathcal{R}}{4} - \frac{\Lambda}{2} - \tau' \bar{\tau}' \right) d^2 A. \quad (15) \end{aligned}$$

These are thus the general pair of integral formulas on a hypersurface based on the Nester-Witten identity, including a cosmological constant $\Lambda \in \mathbb{R}$. With regard to the mass-loss formula, since the mass aspect (at least, for the $\Lambda = 0$ case) involving $\Psi_2^o + \sigma^o \bar{\sigma}^o$ appears in the spin coefficient ρ' , we are most interested in the rate of change of this quantity over different surfaces of constant u on null infinity $\mathcal{I}$. This is the goal of Sec. III, i.e., to evaluate the second integral formula (15) on $\mathcal{I}$.

As mentioned at the beginning of the section, the left-hand sides of the integral formulas are the dL part of the Nester-Witten identity, $dL = S + E$. The E refers to the Einstein tensor, which in this case is just the term involving Λ , and the rest is S . We will be interested in isolating dL , which will be adopted as a generalization of the Bondi mass M_Λ for any $\Lambda \in \mathbb{R}$.

III. EVALUATING THE INTEGRAL FORMULA ON NULL INFINITY WITH $\Lambda \in \mathbb{R}$

A. Null tetrad, spin coefficients, and null rotation

The asymptotic solutions with $\Lambda \in \mathbb{R}$ have recently been worked out in Refs. [15,16]. The coordinates used there are u , r , and x^μ , with μ labeling the two angular coordinates on S_s , u being a retarded null coordinate (a dot above a quantity represents a partial derivative of that quantity with respect to u), and r being an affine parameter of the null geodesics generating the outgoing null hypersurfaces $u = \text{constant}$. Null infinity $\mathcal{I}$ is the hypersurface obtained by taking the limit where $r \rightarrow \infty$. Anyway, the null tetrad vectors are [36]

$$\vec{l}_{\text{Saw}} = \vec{\partial}_r \quad (16)$$

$$\vec{n}_{\text{Saw}} = \vec{\partial}_u + U \vec{\partial}_r + X^\mu \vec{\partial}_\mu \quad (17)$$

$$\vec{m}_{\text{Saw}} = \omega \vec{\partial}_r + \xi^\mu \vec{\partial}_\mu \quad (18) \quad \vec{l} = \vec{l}_{\text{Saw}} \quad (28)$$

$$\vec{m}_{\text{Saw}} = \bar{\omega} \vec{\partial}_r + \bar{\xi}^\mu \vec{\partial}_\mu, \quad (19) \quad \vec{n} = \vec{n}_{\text{Saw}} + \bar{c} \vec{m}_{\text{Saw}} + c \vec{\bar{m}}_{\text{Saw}} + c \bar{c} \vec{l}_{\text{Saw}} \quad (29)$$

where

$$U = \frac{\Lambda}{6} r^2 - \left(\frac{1}{2} K + \frac{\Lambda}{2} |\sigma^o|^2 \right) - \text{Re}(\Psi_2^o) r^{-1} \quad (20)$$

$$+ \left(\frac{1}{3} \text{Re}(\delta' \Psi_1^o) - \frac{\Lambda}{18} \text{Re}(\bar{\sigma}^o \Psi_0^o) \right) r^{-2} + O(r^{-3}) \quad (20)$$

$$X^\mu = O(r^{-3}) \quad (21) \quad \vec{l} = \vec{\partial}_r \quad (32)$$

$$\omega = \delta' \sigma^o r^{-1} - \left(\sigma^o \delta \bar{\sigma}^o + \frac{1}{2} \Psi_1^o \right) r^{-2} + O(r^{-3}) \quad (22) \quad \vec{n} = \vec{\partial}_u + (U - \omega \bar{\omega}) \vec{\partial}_r + (X^\mu - 2 \text{Re}(\bar{\omega} \xi^\mu)) \vec{\partial}_\mu \quad (33)$$

$$\xi^\mu = (\xi^\mu)^o r^{-1} - \sigma^o (\bar{\xi}^\mu)^o r^{-2} + O(r^{-3}), \quad (23) \quad \vec{m} = \xi^\mu \vec{\partial}_\mu \quad (34)$$

with K being the Gauss curvature of the 2-surfaces of constant u on $\mathcal{I}$:

$$\frac{\partial K}{\partial u} = \frac{2\Lambda}{3} \text{Re}(\delta^2 \bar{\sigma}^o), \text{ i.e.} \quad (24)$$

$$K = \Theta(x^\mu) + \frac{2\Lambda}{3} \int \text{Re}(\delta^2 \bar{\sigma}^o) du. \quad (25)$$

The free function $\Theta(x^\mu)$ was set to 1 in Ref. [15] so that when $\Lambda = 0$ one then recovers the asymptotically flat result in which a conformal transformation of 2-surfaces would turn these surfaces of constant u on $\mathcal{I}$ into *round* 2-spheres [37]. With a nonzero $\Lambda \in \mathbb{R}$, however, these 2-surfaces of constant u on $\mathcal{I}$ are not round 2-spheres. Instead, they are topological 2-spheres. Hence, the δ and δ' operators are defined on these topological 2-spheres of constant u on $\mathcal{I}$ [15,16],

$$\delta \eta := (\xi^\mu)^o \frac{\partial \eta}{\partial x^\mu} + 2s \bar{\alpha}^o \eta \quad (26)$$

$$\delta' \eta := (\bar{\xi}^\mu)^o \frac{\partial \eta}{\partial x^\mu} - 2s \alpha^o \eta, \quad (27)$$

where η is a spin-weighted quantity with spin weight s [27] and α^o is the leading-order term of the spin coefficient α (when expanded in inverse powers of r away from $\mathcal{I}$) [15]. For brevity, we sometimes denote the partial derivative by ∂ with a subscript indicative of the coordinate, i.e., $\partial/\partial u = \partial_u$, $\partial/\partial r = \partial_r$, and $\partial/\partial x^\mu = \partial_\mu$.

Now, the setup by Frauendiener employed a null tetrad in which $\vec{m}$ and $\vec{\bar{m}}$ are tangential to S_s , i.e., they do not have any $\vec{\partial}_r$ component [26]. To convert the null tetrad and spin coefficients found in Refs. [15,16] so that we may apply them here to evaluate Eq. (15), we perform a null rotation around $\vec{l}$,

where c is a complex function. Letting $c = -\omega$, the new null tetrad vectors are

$$\vec{l} = \vec{\partial}_r \quad (32)$$

$$\vec{n} = \vec{\partial}_u + (U - \omega \bar{\omega}) \vec{\partial}_r + (X^\mu - 2 \text{Re}(\bar{\omega} \xi^\mu)) \vec{\partial}_\mu \quad (33)$$

$$\vec{m} = \xi^\mu \vec{\partial}_\mu \quad (34)$$

$$\vec{\bar{m}} = \bar{\xi}^\mu \vec{\partial}_\mu. \quad (35)$$

The relevant spin coefficients (for evaluating the integral formula here) taken from Ref. [15] are

$$\rho_{\text{Saw}} = -r^{-1} - |\sigma^o|^2 r^{-3} + \left(\frac{1}{3} \text{Re}(\bar{\sigma}^o \Psi_0^o) - |\sigma^o|^4 \right) r^{-5} + O(r^{-6}) \quad (36)$$

$$\rho'_{\text{Saw}} = -\frac{\Lambda}{6} r + \left(\frac{1}{2} K + \frac{\Lambda}{3} |\sigma^o|^2 \right) r^{-1} + (\Psi_2^o + \sigma^o \dot{\sigma}^o) r^{-2} + \left(\frac{1}{2} K |\sigma^o|^2 + \frac{\Lambda}{3} |\sigma^o|^4 + \frac{\Lambda}{9} \text{Re}(\bar{\sigma}^o \Psi_0^o) - \frac{1}{2} \delta' \Psi_1^o \right) r^{-3} + O(r^{-4}) \quad (37)$$

$$\sigma_{\text{Saw}} = \sigma^o r^{-2} + \left(\sigma^o |\sigma^o|^2 - \frac{1}{2} \Psi_0^o \right) r^{-4} + O(r^{-5}) \quad (38)$$

$$\sigma'_{\text{Saw}} = -\frac{\Lambda}{6} \bar{\sigma}^o - \dot{\sigma}^o r^{-1} - \left(\frac{1}{2} K \bar{\sigma}^o + \frac{\Lambda}{3} \bar{\sigma} |\sigma^o|^2 + \frac{\Lambda}{12} \bar{\Psi}_0^o \right) r^{-2} + O(r^{-3}) \quad (39)$$

$$\text{Re}(\gamma_{\text{Saw}}) = -\frac{\Lambda}{6} r - \frac{1}{2} \text{Re}(\Psi_2^o) r^{-2} + \left(\frac{1}{3} \text{Re}(\delta' \Psi_1^o) - \frac{\Lambda}{18} \text{Re}(\bar{\sigma}^o \Psi_0^o) \right) r^{-3} + O(r^{-4}) \quad (40)$$

$$\gamma'_{\text{Saw}} = 0 \quad (41)$$

$$\tau_{\text{Saw}} = O(r^{-3}) \quad (42)$$

$$\tau'_{\text{Saw}} = 0 \quad (43)$$

$$\alpha_{\text{Saw}} = \alpha^o r^{-1} + \bar{\alpha}^o \bar{\sigma}^o r^{-2} + O(r^{-3}) \quad (44)$$

$$\alpha'_{\text{Saw}} = \bar{\alpha}^o r^{-1} + \alpha^o \sigma^o r^{-2} + O(r^{-3}). \quad (45)$$

Under the required null rotation, the relevant spin coefficients transform as

$$\rho = \rho_{\text{Saw}} \quad (46)$$

$$\rho' = \rho'_{\text{Saw}} - \bar{\omega}^2 \sigma_{\text{Saw}} - 2\bar{\omega} \alpha'_{\text{Saw}} + \delta \bar{\omega} - \omega D \bar{\omega} \quad (47)$$

$$\sigma = \sigma_{\text{Saw}} \quad (48)$$

$$\sigma' = \sigma'_{\text{Saw}} + 2\bar{\omega} \alpha_{\text{Saw}} - \bar{\omega}^2 \rho_{\text{Saw}} + \delta' \bar{\omega} - \bar{\omega} D \bar{\omega} \quad (49)$$

$$\gamma = \gamma_{\text{Saw}} - \omega \alpha_{\text{Saw}} + \bar{\omega} \alpha'_{\text{Saw}} - \bar{\omega} \tau_{\text{Saw}} + \omega \bar{\omega} \rho_{\text{Saw}} + \bar{\omega}^2 \sigma_{\text{Saw}} \quad (50)$$

$$\gamma' = 0 \quad (51)$$

$$\tau = \tau_{\text{Saw}} - \omega \rho_{\text{Saw}} - \bar{\omega} \sigma_{\text{Saw}} \quad (52)$$

$$\tau' = D \bar{\omega}. \quad (53)$$

In the above, D , D' , δ , and δ' are directional derivatives along $\vec{l}_{\text{Saw}}$, $\vec{n}_{\text{Saw}}$, $\vec{m}_{\text{Saw}}$, and $\vec{\bar{m}}_{\text{Saw}}$, respectively. Therefore, the null-rotated spin coefficients expressed in terms of the null tetrad given by Eqs. (32)–(35) are

$$\rho = -r^{-1} - |\sigma^o|^2 r^{-3} + \left(\frac{1}{3} \text{Re}(\bar{\sigma}^o \Psi_0^o) - |\sigma^o|^4 \right) r^{-5} + O(r^{-6}) \quad (54)$$

$$\begin{aligned} \rho' = & -\frac{\Lambda}{6} r + \left(\frac{1}{2} K + \frac{\Lambda}{3} |\sigma^o|^2 \right) r^{-1} + (\Psi_2^o + \sigma^o \dot{\bar{\sigma}}^o + \delta^2 \bar{\sigma}^o) r^{-2} \\ & + \left(\frac{1}{2} K |\sigma^o|^2 + \frac{\Lambda}{3} |\sigma^o|^4 + \frac{\Lambda}{9} \text{Re}(\bar{\sigma}^o \Psi_0^o) - \text{Re}(\delta' \Psi_1^o) \right. \\ & \left. - |\delta' \sigma^o|^2 - 2 \text{Re}(\sigma^o \delta' \bar{\sigma}^o) \right) r^{-3} + O(r^{-4}) \end{aligned} \quad (55)$$

$$\sigma = \sigma^o r^{-2} + \left(\sigma^o |\sigma^o|^2 - \frac{1}{2} \Psi_0^o \right) r^{-4} + O(r^{-5}) \quad (56)$$

$$\begin{aligned} \sigma' = & -\frac{\Lambda}{6} \bar{\sigma}^o - \dot{\bar{\sigma}}^o r^{-1} - \left(\frac{1}{2} K \bar{\sigma}^o + \frac{\Lambda}{3} \bar{\sigma}^o |\sigma^o|^2 \right. \\ & \left. - \delta' \bar{\sigma}^o + \frac{\Lambda}{12} \bar{\Psi}_0^o \right) r^{-2} + O(r^{-3}) \end{aligned} \quad (57)$$

$$\begin{aligned} \text{Re}(\gamma) = & -\frac{\Lambda}{6} r - \frac{1}{2} \text{Re}(\Psi_2^o) r^{-2} \\ & + \left(\frac{1}{3} \text{Re}(\delta' \Psi_1^o) - |\delta' \sigma^o|^2 - \frac{\Lambda}{18} \text{Re}(\bar{\sigma}^o \Psi_0^o) \right) r^{-3} \\ & + O(r^{-4}) \end{aligned} \quad (58)$$

$$\gamma' = 0 \quad (59)$$

$$\tau = \delta' \sigma^o r^{-2} + O(r^{-3}) \quad (60)$$

$$\tau' = -\delta \bar{\sigma}^o r^{-2} + O(r^{-3}). \quad (61)$$

Note that in this null tetrad employed by Frauendiener ρ' is real [26], so $\Psi_2^o + \sigma^o \dot{\bar{\sigma}}^o + \delta^2 \bar{\sigma}^o = \text{Re}(\Psi_2^o + \sigma^o \dot{\bar{\sigma}}^o + \delta^2 \bar{\sigma}^o)$.

B. Hypersurface with $\vec{Z} = \vec{n} - (U - \omega \bar{\omega}) \vec{l}$ and the s derivative of the area element

To obtain the mass-loss formula, the goal is to have a derivative of the mass aspect $\Psi_2^o + \sigma^o \dot{\bar{\sigma}}^o$ [which appears in the r^{-2} order of ρ' ; see Eq. (55)] involving different values of u on $\mathcal{I}$. The hypersurface $\mathcal{I}$ is reached by taking the limit $r \rightarrow \infty$, but before taking this limit, we have to work with some hypersurface Σ_r having finite r (i.e., Σ_∞ is $\mathcal{I}$). The need for a u derivative implies that this should involve a derivative along (the null-rotated) $\vec{n}$, i.e., $D' = \nabla_a n^a$ (where this D' is along the null-rotated $\vec{n}$, not $\vec{n}_{\text{Saw}}$). The simplest way to have D' would be to consider a hypersurface Σ_r with the vector $\vec{Z}$ (representing the outward or inward flow of the topological 2-spheres S_s that foliate Σ_r) being $\vec{Z} = \vec{n} = \bar{\partial}_u + (U - \omega \bar{\omega}) \bar{\partial}_r + (X^\mu - 2 \text{Re}(\bar{\omega} \xi^\mu)) \bar{\partial}_\mu$. Then, since $\vec{Z} = Z \vec{l} + Z' \vec{n}$, we get $Z = 0$ and $Z' = 1$. With this, the s derivative would be $\partial/\partial u + (U - \omega \bar{\omega}) \partial/\partial r + (X^\mu - 2 \text{Re}(\bar{\omega} \xi^\mu)) \partial/\partial x_\mu$. This would indeed work (as we have verified) and perhaps requires the least amount of calculations since $Z = 0$ would kill off terms involving the Ricci scalar $\mathcal{R}$ and the spin coefficient τ' in the integral formula as can be seen in Eq. (15).

Now, we wish to follow the setup here with $\Lambda \in \mathbb{R}$ as closely as possible to the asymptotically flat case. With a null $\mathcal{I}$ when $\Lambda = 0$, there is then a canonical choice for $\vec{Z}$, viz., $\vec{Z} = \bar{\partial}_u$ as was done by Frauendiener [26]. This choice of $\vec{Z}$ implies that the foliation of the hypersurface under consideration by S_s is the one in which S_s are the 2-surfaces of constant u (denoted by S_u), whereas other choices of $\vec{Z}$ would foliate the hypersurface differently. As we are interested in the mass-loss formula defined on a constant u cut on $\mathcal{I}$, this is the geometrically relevant choice for $\vec{Z}$.

Ergo, let us consider having $\vec{Z} = \vec{n} - (U - \omega \bar{\omega}) \vec{l} = \bar{\partial}_u + (X^\mu - 2 \text{Re}(\bar{\omega} \xi^\mu)) \bar{\partial}_\mu$, which is the same $\vec{Z}$ taken by Frauendiener for the asymptotically flat case [26], i.e., $Z = -U + \omega \bar{\omega}$ and $Z' = 1$. As he had explained in his

derivation of the integral formulas, the angular terms $\vec{\partial}_\mu$ in $\vec{Z}$ give zero contribution because they are integrated away as boundary terms on the topological 2-sphere (which has no boundary). This $\vec{Z}$ is thus effectively $\vec{\partial}_u$. We shall proceed to evaluate the s derivative (which is $Z^a \nabla_a$) of the area element d^2A of the 2-surfaces that foliate the hypersurface Σ_r . In the asymptotically flat case, the s derivative of such an area element is zero if one foliates $\mathcal{I}$ by round spheres. With $\Lambda \neq 0$, however, $\mathcal{I}$ cannot be foliated by round spheres if $\sigma^o \neq 0$, i.e., when there is Bondi news [15], and consequently we need to work this out explicitly.

First, this area element for the topological 2-sphere S_s is $d^2A = -im_a \wedge \bar{m}_b$ [38]. Since the s derivative is a directional derivative along $\vec{Z}$, this is equivalent to the Lie derivative along $\vec{Z}$:

$$\frac{d(d^2A)}{ds} = -i\mathcal{L}_{\vec{Z}}(m_a \wedge \bar{m}_b) \quad (62)$$

$$= -i\mathcal{L}_{\vec{Z}}m_a \wedge \bar{m}_b - im_a \wedge \mathcal{L}_{\vec{Z}}\bar{m}_b. \quad (63)$$

Well,

$$\mathcal{L}_{\vec{Z}}m_a = Z^b \nabla_b m_a + m_b \nabla_a Z^b \quad (64)$$

$$= (n^b - (U - \omega\bar{\omega})l^b) \nabla_b m_a + m_b \nabla_a (n^b - (U - \omega\bar{\omega})l^b) \quad (65)$$

$$= D'm_a - (U - \omega\bar{\omega})Dm_a + m_b \nabla_a n^b - (U - \omega\bar{\omega})m_b \nabla_a l^b, \quad (66)$$

using $\nabla_a(fV^b) = f\nabla_a V^b + V^b \nabla_a f$ and $m_b l^b = 0$. With $D'm_a = 2i\text{Im}(\gamma)m_a$ and $Dm_a = -2i\text{Im}(\gamma')m_a$ [28],

$$\mathcal{L}_{\vec{Z}}m_a = 2i\text{Im}(\gamma)m_a + 2i(U - \omega\bar{\omega})\text{Im}(\gamma')m_a + m_b \nabla_a n^b - (U - \omega\bar{\omega})m_b \nabla_a l^b. \quad (67)$$

Then,

$$(\mathcal{L}_{\vec{Z}}m_a)\bar{m}^a = -2i\text{Im}(\gamma) - 2i(U - \omega\bar{\omega})\text{Im}(\gamma') + m_b \delta' n^b - (U - \omega\bar{\omega})m_b \delta' l^b \quad (68)$$

$$= -2i\text{Im}(\gamma) - 2i(U - \omega\bar{\omega})\text{Im}(\gamma') + \bar{\rho}' - (U - \omega\bar{\omega})\rho, \quad \text{and} \quad (69)$$

$$(\mathcal{L}_{\vec{Z}}m_a)m^a = m_b \delta n^b - (U - \omega\bar{\omega})m_b \delta l^b \quad (70)$$

$$= \bar{\sigma}' - (U - \omega\bar{\omega})\sigma, \quad \text{i.e.,} \quad (71)$$

$$\mathcal{L}_{\vec{Z}}m_a = (2i\text{Im}(\gamma) + 2i(U - \omega\bar{\omega})\text{Im}(\gamma') - \bar{\rho}' + (U - \omega\bar{\omega})\rho)m_a - (\bar{\sigma}' - (U - \omega\bar{\omega})\sigma)\bar{m}_a, \quad (72)$$

where the spin coefficients ρ , ρ' , σ , and σ' are defined as $m_b \delta' l^b$, $\bar{m}_b \delta n^b$, $m_b \delta l^b$, and $\bar{m}_b \delta' n^b$ respectively, with $\vec{m}$ and $\vec{\bar{m}}$ satisfying the orthonormalization $m^a \bar{m}_a = -1$ and $m^a m_a = \bar{m}^a \bar{m}_a = 0$ [28]. Similarly (or just taking the complex conjugate), we have

$$\begin{aligned} \mathcal{L}_{\vec{Z}}\bar{m}_a &= -(\sigma' - (U - \omega\bar{\omega})\bar{\sigma})\bar{m}_a \\ &\quad + (-2i\text{Im}(\gamma) - 2i(U - \omega\bar{\omega})\text{Im}(\gamma')) \\ &\quad - \rho' + (U - \omega\bar{\omega})\bar{\rho})\bar{m}_a. \end{aligned} \quad (73)$$

Hence,

$$\begin{aligned} \frac{d(d^2A)}{ds} &= (-\bar{\rho}' + (U - \omega\bar{\omega})\rho - \rho' \\ &\quad + (U - \omega\bar{\omega})\bar{\rho})(-im_a \wedge \bar{m}_b) \end{aligned} \quad (74)$$

$$= 2\text{Re}((U - \omega\bar{\omega})\rho - \rho')d^2A \quad (75)$$

$$= 2((U - \omega\bar{\omega})\rho - \rho')d^2A, \quad (76)$$

where we recall that ρ and ρ' in Eqs. (54) and (55), respectively, are real in this null tetrad given by Eqs. (32)–(35).

With this $\vec{Z} = \vec{n} - (U - \omega\bar{\omega})\vec{l}$, the integral formulas in Eqs. (14) and (15) are

$$\begin{aligned} &\oint \frac{d\rho}{ds} d^2A + 2 \oint \rho((U - \omega\bar{\omega})\rho - \rho')d^2A \\ &= \oint \rho(2\text{Re}(\gamma) + (U - \omega\bar{\omega})\rho)d^2A - \oint (U - \omega\bar{\omega})\sigma\bar{\sigma}d^2A \\ &\quad + \oint \left(\frac{\mathcal{R}}{4} - \frac{\Lambda}{2} - \tau\bar{\tau}\right)d^2A, \quad \text{and} \end{aligned} \quad (77)$$

$$\begin{aligned} &\oint \frac{d\rho'}{ds} d^2A + 2 \oint \rho'((U - \omega\bar{\omega})\rho - \rho')d^2A \\ &= - \oint \rho'(2\text{Re}(\gamma) + \rho')d^2A + \oint \sigma'\bar{\sigma}'d^2A \\ &\quad - \oint (U - \omega\bar{\omega})\left(\frac{\mathcal{R}}{4} - \frac{\Lambda}{2} - \tau'\bar{\tau}'\right)d^2A. \end{aligned} \quad (78)$$

C. Evaluating the first integral formula up to order r^{-4}

The mass-loss formula arises from the second integral formula Eq. (78) (at the r^{-2} order of the integrands). This choice of $\vec{Z}$ requires knowledge of the integral of $\mathcal{R}$ up to order r^{-4} because the lowest-order term of $Z = -U + \omega\bar{\omega}$ is $-\Lambda r^2/6$. Interestingly, this can be obtained from the first integral formula (77). By expressing $\mathcal{R}$ in terms of an expansion from $\mathcal{I}$ in inverse powers of r ,

$$\mathcal{R} = 2Kr^{-2} + \mathcal{R}_3^o r^{-3} + \mathcal{R}_4^o r^{-4} + O(r^{-5}), \quad (79)$$

our goal here is to work out the integrals of $\mathcal{R}_3^o$ and $\mathcal{R}_4^o$ using Eq. (77) [39].

We can calculate each integrand term in Eq. (77) up to order $O(r^{-4})$, and the results are listed below:

$$\frac{d\rho}{ds} = -2\text{Re}(\sigma^o \dot{\bar{\sigma}}^o) r^{-3} + O(r^{-5}) \quad (80)$$

$$2\rho((U - \omega\bar{\omega})\rho - \rho') = 2\text{Re}(\sigma^o \dot{\bar{\sigma}}^o + \bar{\partial}^2 \bar{\sigma}^o) r^{-3} - 4 \left(|\bar{\partial}' \sigma^o|^2 + \text{Re}(\sigma^o \bar{\partial}' \bar{\partial} \bar{\sigma}^o) + \frac{1}{3} \text{Re}(\bar{\partial}' \Psi_1^o) \right) r^{-4} + O(r^{-5}) \quad (81)$$

$$\rho(2\text{Re}(\gamma) + (U - \omega\bar{\omega})\rho) = \frac{\Lambda}{2} + \left(-\frac{1}{2}K + \frac{\Lambda}{6} |\sigma^o|^2 \right) r^{-2} + \left(-K |\sigma^o|^2 - \frac{\Lambda}{6} |\sigma^o|^4 + |\bar{\partial}' \sigma^o|^2 - \frac{\Lambda}{6} \text{Re}(\bar{\sigma}^o \Psi_0^o) - \frac{1}{3} \text{Re}(\bar{\partial}' \Psi_1^o) \right) r^{-4} + O(r^{-5}) \quad (82)$$

$$-(U - \omega\bar{\omega})\sigma\bar{\sigma} = -\frac{\Lambda}{6} |\sigma^o|^2 r^{-2} + \left(\frac{1}{2}K |\sigma^o|^2 + \frac{\Lambda}{6} |\sigma^o|^4 + \frac{\Lambda}{6} \text{Re}(\bar{\sigma}^o \Psi_0^o) \right) r^{-4} + O(r^{-5}) \quad (83)$$

$$\frac{\mathcal{R}}{4} - \frac{\Lambda}{2} - \tau\bar{\tau} = -\frac{\Lambda}{2} + \frac{1}{2}Kr^{-2} + \frac{1}{4}\mathcal{R}_3^o r^{-3} + \left(\frac{1}{4}\mathcal{R}_4^o - |\bar{\partial}' \sigma^o|^2 \right) r^{-4} + O(r^{-5}). \quad (84)$$

Therefore, from the first integral formula Eq. (77), the lowest nontrivial order in powers of r^{-1} is

$$\oint \mathcal{R}_3^o d^2A = 0. \quad (85)$$

The next order gives

$$\oint \mathcal{R}_4^o d^2A = \oint 2K |\sigma^o|^2 d^2A. \quad (86)$$

D. Evaluating the second integral formula up to order r^{-2}

Let us now work out all the individual integrand terms in the second integral formula Eq. (78), up to order r^{-2} . Upon evaluating the second integral formula, we will find that all terms of lower orders of r cancel out, leaving a relationship at order r^{-2} . Note that d^2A is of order r^2 , so this will result in an integral formula on Σ_r containing terms independent of r plus $O(r^{-1})$ terms. In the limit where $r \rightarrow \infty$, we will get the desired mass-loss formula with $\Lambda \in \mathbb{R}$ in which the hypersurface Σ_∞ is null infinity $\mathcal{I}$ [and the $O(r^{-1})$ terms all vanish].

Here are the results of the calculations:

$$\frac{d\rho'}{ds} = \frac{\Lambda}{3} \text{Re}(2\sigma^o \dot{\bar{\sigma}}^o + \bar{\partial}^2 \bar{\sigma}^o) r^{-1} + \frac{\partial}{\partial u} (\Psi_2^o + \sigma^o \dot{\bar{\sigma}}^o + \bar{\partial}^2 \bar{\sigma}^o) r^{-2} + O(r^{-3}) \quad (87)$$

$$2\rho'((U - \omega\bar{\omega})\rho - \rho') = \frac{\Lambda}{3} \text{Re}(\sigma^o \dot{\bar{\sigma}}^o + \bar{\partial}^2 \bar{\sigma}^o) r^{-1} - \frac{2\Lambda}{3} \left(|\bar{\partial}' \sigma^o|^2 + \text{Re}(\sigma^o \bar{\partial}' \bar{\partial} \bar{\sigma}^o) + \frac{1}{3} \text{Re}(\bar{\partial}' \Psi_1^o) \right) r^{-2} + O(r^{-3}) \quad (88)$$

$$\begin{aligned} -\rho'(2\text{Re}(\gamma) + \rho') &= -\frac{\Lambda^2}{12} r^2 + \left(\frac{\Lambda}{3}K + \frac{2\Lambda^2}{9} |\sigma^o|^2 \right) + \left(\frac{\Lambda}{2} \text{Re}(\Psi_2^o) + \frac{2\Lambda}{3} \text{Re}(\sigma^o \dot{\bar{\sigma}}^o + \bar{\partial}^2 \bar{\sigma}^o) \right) r^{-1} \\ &\quad + \left(-\frac{1}{4}K^2 + \frac{\Lambda^2}{9} |\sigma^o|^4 - \Lambda |\bar{\partial}' \sigma^o|^2 - \frac{4\Lambda}{3} \text{Re}(\sigma^o \bar{\partial}' \bar{\partial} \bar{\sigma}^o) + \frac{\Lambda^2}{18} \text{Re}(\bar{\sigma}^o \Psi_0^o) - \frac{5\Lambda}{9} \text{Re}(\bar{\partial}' \Psi_1^o) \right) r^{-2} + O(r^{-3}) \end{aligned} \quad (89)$$

$$\sigma' \bar{\sigma}' = \frac{\Lambda^2}{36} |\sigma^o|^2 + \frac{\Lambda}{3} \text{Re}(\sigma^o \dot{\bar{\sigma}}^o) r^{-1} + \left(|\dot{\sigma}^o|^2 + \frac{\Lambda}{6} K |\sigma^o|^2 + \frac{\Lambda^2}{9} |\sigma^o|^4 - \frac{\Lambda}{3} \text{Re}(\sigma^o \delta' \bar{\delta} \bar{\sigma}^o) + \frac{\Lambda^2}{36} \text{Re}(\bar{\sigma}^o \Psi_0^o) \right) r^{-2} + O(r^{-3}) \quad (90)$$

$$\begin{aligned} -(U - \omega \bar{\omega}) \left(\frac{\mathcal{R}}{4} - \frac{\Lambda}{2} - \tau' \bar{\tau}' \right) &= \frac{\Lambda^2}{12} r^2 - \left(\frac{\Lambda}{3} K + \frac{\Lambda^2}{4} |\sigma^o|^2 \right) - \frac{\Lambda}{2} \left(\text{Re}(\Psi_2^o) + \frac{1}{12} \mathcal{R}_3^o \right) r^{-1} \left(\frac{1}{4} K^2 + \frac{\Lambda}{4} K |\sigma^o|^2 - \frac{\Lambda}{24} \mathcal{R}_4^o \right. \\ &\quad \left. - \frac{\Lambda}{3} |\delta' \sigma^o|^2 - \frac{\Lambda^2}{36} \text{Re}(\bar{\sigma}^o \Psi_0^o) + \frac{\Lambda}{6} \text{Re}(\delta' \Psi_1^o) \right) r^{-2} + O(r^{-3}). \end{aligned} \quad (91)$$

Incidentally, using the definitions of the δ and δ' operators in Eqs. (26) and (27), we find that

$$\partial_u \delta^2 \bar{\sigma}^o = \partial_u [(\xi^\mu)^o \partial_\mu (\delta \bar{\sigma}^o) - 2 \bar{\alpha}^o \delta \bar{\sigma}^o] \quad (92)$$

$$= (\dot{\xi}^\mu)^o \partial_\mu (\delta \bar{\sigma}^o) - 2 \dot{\bar{\alpha}}^o \delta \bar{\sigma}^o + (\xi^\mu)^o \partial_\mu (\partial_u (\delta \bar{\sigma}^o)) - 2 \bar{\alpha}^o \partial_u (\delta \bar{\sigma}^o) \quad (93)$$

$$= -\frac{\Lambda}{3} \sigma^o [(\bar{\xi}^\mu)^o \partial_\mu (\delta \bar{\sigma}^o) + 2 \alpha^o \delta \bar{\sigma}^o] - \frac{\Lambda}{3} |\delta' \sigma^o|^2 + \delta (\partial_u (\delta \bar{\sigma}^o)) \quad (94)$$

$$= -\frac{\Lambda}{3} \sigma^o \delta' \bar{\delta} \bar{\sigma}^o - \frac{\Lambda}{3} |\delta' \sigma^o|^2 + \delta (\partial_u (\delta \bar{\sigma}^o)). \quad (95)$$

In the above, we went from the second to the third line by making use of the u derivatives of $(\xi^\mu)^o$ and α^o , being

$$(\dot{\xi}^\mu)^o = -\frac{\Lambda}{3} \sigma^o (\bar{\xi}^\mu)^o \quad (96)$$

$$\dot{\alpha}^o = \frac{\Lambda}{3} \bar{\alpha}^o \bar{\sigma}^o + \frac{\Lambda}{6} \delta \bar{\sigma}^o, \quad (97)$$

respectively [15,16]. (These follow from the equations of the Newman-Penrose formalism, for $D' \xi^\mu$ and $D' \alpha$.) This result would allow us to interchange the order of taking the u derivative of $\delta^2 \bar{\sigma}^o$ with the “left” δ to end up with $\delta \partial_u \delta \bar{\sigma}^o$ plus terms that eliminate each other upon integration over a compact surface. Since $\delta \partial_u \delta \bar{\sigma}^o$ itself would vanish when integrated, then the u derivative of $\delta^2 \bar{\sigma}^o$ does not contribute to the integration. [This u derivative of $\delta^2 \bar{\sigma}^o$ would appear in the u derivative of the mass aspect, found in the r^{-2} order of ρ' —see Eq. (87).]

Ergo, putting everything together into Eq. (78), we find that all terms of orders r^2 , r , 1, and r^{-1} exactly cancel out, giving

$$- \oint \left(\frac{\partial}{\partial u} (\Psi_2^o + \sigma^o \dot{\bar{\sigma}}^o) r^{-2} + O(r^{-3}) \right) d^2 A \quad (98)$$

$$\begin{aligned} &= - \oint \left(\left(|\dot{\sigma}^o|^2 + \frac{\Lambda}{3} K |\sigma^o|^2 + \frac{\Lambda}{3} |\delta' \sigma^o|^2 + \frac{2\Lambda^2}{9} |\sigma^o|^4 \right. \right. \\ &\quad \left. \left. + \frac{\Lambda^2}{18} \text{Re}(\bar{\sigma}^o \Psi_0^o) \right) r^{-2} + O(r^{-3}) \right) d^2 A, \end{aligned} \quad (99)$$

where terms involving an overall δ and δ' integrate to zero over the compact 2-surface that has no boundary and

integration by parts have been applied to the terms involving $\sigma^o \delta' \bar{\delta} \bar{\sigma}^o$.

With $d^2 A = r^2 d^2 S + O(r)$, where $d^2 S$ is the area element of the topological 2-sphere of constant u on $\mathcal{I}$, and then taking the limit as $r \rightarrow \infty$ so that Σ_r becomes null infinity $\mathcal{I}$, we arrive at

$$\begin{aligned} &- \oint \left(\frac{\partial}{\partial u} (\Psi_2^o + \sigma^o \dot{\bar{\sigma}}^o) \right) d^2 S \\ &= - \oint \left(|\dot{\sigma}^o|^2 + \frac{\Lambda}{3} K |\sigma^o|^2 + \frac{\Lambda}{3} |\delta' \sigma^o|^2 + \frac{2\Lambda^2}{9} |\sigma^o|^4 \right. \\ &\quad \left. + \frac{\Lambda^2}{18} \text{Re}(\bar{\sigma}^o \Psi_0^o) \right) d^2 S. \end{aligned} \quad (100)$$

One can then pull the u derivative out of the surface integral [note that $\partial(d^2 S)/\partial u = 0$, with a proof given in Appendix B] and produce the identical mass-loss formula as reported in Eq. (127) in Ref. [15], which we express here in terms of $M_B = -A^{-1} \oint (\Psi_2^o + \sigma^o \dot{\bar{\sigma}}^o) d^2 S$ (the expression for the Bondi mass in the asymptotically flat case):

$$\begin{aligned} \frac{dM_B}{du} &= -\frac{1}{A} \oint \left(|\dot{\sigma}^o|^2 + \frac{\Lambda}{3} K |\sigma^o|^2 + \frac{\Lambda}{3} |\delta' \sigma^o|^2 \right. \\ &\quad \left. + \frac{2\Lambda^2}{9} |\sigma^o|^4 + \frac{\Lambda^2}{18} \text{Re}(\bar{\sigma}^o \Psi_0^o) \right) d^2 S. \end{aligned} \quad (101)$$

Here, $A = 4\pi$ is the area of the topological 2-sphere of constant u on $\mathcal{I}$. Incidentally, the expression for dL of the Nester-Witten identity is precisely the rate of change of the Bondi mass for the asymptotically flat case, dM_B/du .

IV. IDENTITY FOR $K|\sigma^o|^2$: QUADRUPOLE GRAVITATIONAL WAVES

A. Identity for $K|\sigma^o|^2$

Let $\eta(u, \theta, \phi)$ be a spin-weighted quantity with spin weight $s = (p - q)/2$ [i.e., of type (p, q)], defined on $\mathcal{I}$ (so η is independent of r). We can derive an identity for the Gauss curvature K of the topological 2-sphere of constant u on $\mathcal{I}$ using the commutator of the $\bar{\partial}$ and ∂' operators [27,40], as

$$|\bar{\partial}\eta|^2 - |\partial'\eta|^2 = \bar{\partial}\eta\partial'\bar{\eta} - \partial'\eta\bar{\partial}\bar{\eta} \quad (102)$$

$$= \partial'(\bar{\eta}\partial\eta) - \bar{\partial}(\bar{\eta}\partial'\eta) + \bar{\eta}[\bar{\partial}, \partial']\eta \quad (103)$$

$$\begin{aligned} &= \partial'(\bar{\eta}\partial\eta) - \bar{\partial}(\bar{\eta}\partial'\eta) \\ &\quad + p\left(\rho\rho' - \sigma\sigma' + \Psi_2 - \Phi_{11} - \frac{\Lambda}{6}\right)\eta\bar{\eta} \\ &\quad - q\left(\bar{\rho}\bar{\rho}' - \bar{\sigma}\bar{\sigma}' + \bar{\Psi}_2 - \Phi_{11} - \frac{\Lambda}{6}\right)\eta\bar{\eta}, \end{aligned} \quad (104)$$

where we have used

$$\begin{aligned} [\bar{\partial}, \partial'] &= -2i\text{Im}(\rho')\mathfrak{p} + 2i\text{Im}(\rho)\mathfrak{p}' \\ &\quad + p\left(\rho\rho' - \sigma\sigma' + \Psi_2 - \Phi_{11} - \frac{\Lambda}{6}\right) \\ &\quad - q\left(\bar{\rho}\bar{\rho}' - \bar{\sigma}\bar{\sigma}' + \bar{\Psi}_2 - \Phi_{11} - \frac{\Lambda}{6}\right) \end{aligned} \quad (105)$$

(which is Eq. (4.14.1) from Ref. [27]) in the last line with the term $-2i\text{Im}(\rho')\mathfrak{p}$ being zero because $\mathfrak{p}$ is a partial derivative with respect to r but η is independent of r (well, $\mathfrak{p} = D = \partial/\partial r$ since $\gamma' = 0$) and the term $2i\text{Im}(\rho)\mathfrak{p}'$ being zero because ρ is real. Since the left-hand side is manifestly real, then the right-hand side must also be real,

$$\begin{aligned} |\bar{\partial}\eta|^2 - |\partial'\eta|^2 &= \text{Re}(\partial'(\bar{\eta}\partial\eta) - \bar{\partial}(\bar{\eta}\partial'\eta)) \\ &\quad + 2s\text{Re}\left(\rho\rho' - \sigma\sigma' + \Psi_2 - \Phi_{11} - \frac{\Lambda}{6}\right)\eta\bar{\eta} \end{aligned} \quad (106)$$

$$= \text{Re}(\partial'(\bar{\eta}\partial\eta) - \bar{\partial}(\bar{\eta}\partial'\eta)) - sK|\eta|^2, \quad (107)$$

where $2s = p - q$ and $-K = 2\text{Re}(\rho\rho' - \sigma\sigma' + \Psi_2 - \Phi_{11} - \Lambda/6)$. Integrating over a topological 2-sphere of constant u on $\mathcal{I}$ (which has no boundary, so the terms with an overall $\bar{\partial}$ or ∂' derivative integrate to zero) gives the following identity:

$$\int_{\mathcal{I}} K|\eta|^2 d^2S = \int_{\mathcal{I}} |\partial'\eta|^2 d^2S - \int_{\mathcal{I}} |\bar{\partial}\eta|^2 d^2S. \quad (108)$$

For $\eta = \sigma^o$ that has spin weight $s = 2$, we have

$$\frac{\Lambda}{3} \int_{\mathcal{I}} K|\sigma^o|^2 d^2S = \frac{\Lambda}{6} \int_{\mathcal{I}} |\partial'\sigma^o|^2 d^2S - \frac{\Lambda}{6} \int_{\mathcal{I}} |\bar{\partial}\sigma^o|^2 d^2S. \quad (109)$$

With this, we can replace the term involving the Gauss curvature in the mass-loss formula (101) to obtain [41]

$$\begin{aligned} \frac{dM_B}{du} &= -\frac{1}{4\pi} \int_{\mathcal{I}} \left(|\dot{\sigma}^o|^2 + \frac{\Lambda}{2} |\partial'\sigma^o|^2 - \frac{\Lambda}{6} |\bar{\partial}\sigma^o|^2 + \frac{2\Lambda^2}{9} |\sigma^o|^4 \right. \\ &\quad \left. + \frac{\Lambda^2}{18} \text{Re}(\bar{\sigma}^o \Psi_0^o) \right) d^2S. \end{aligned} \quad (110)$$

B. Quadrupole gravitational waves

In the absence of incoming radiation (so that $\Psi_0^o = 0$), the mass-loss formula (110) reads

$$\begin{aligned} \frac{dM_B}{du} &= -\frac{1}{4\pi} \int_{\mathcal{I}} \left(|\dot{\sigma}^o|^2 + \frac{\Lambda}{2} |\partial'\sigma^o|^2 - \frac{\Lambda}{6} |\bar{\partial}\sigma^o|^2 \right. \\ &\quad \left. + \frac{2\Lambda^2}{9} |\sigma^o|^4 \right) d^2S. \end{aligned} \quad (111)$$

We see that for $\Lambda > 0$ we have a *negative-definite* term $|\bar{\partial}\sigma^o|^2$, which is fine as long as the *overall* expression on the right-hand side results in a mass loss of M_B such that the gravitational waves given off by an isolated system carry away a positive-definite energy.

Recall that the shear σ^o is a spin-weighted quantity with spin weight $s = 2$ and $\bar{\partial}\sigma^o$ has spin weight $s = 3$ since $\bar{\partial}$ raises the spin weight by 1 [27,28]. When one studies a compact system in linearized theory, one can carry out a multipole expansion. (See, for instance, Ref. [42] for a standard textbook treatment in the $\Lambda = 0$ setup. For recent developments on the quadrupole formula with $\Lambda > 0$, see Refs. [43–45].) Spin-weighted quantities may be decomposed into spin-weighted spherical harmonics [40,46]. For a quantity with spin weight s , it is expressible as a linear combination of these spin-weighted spherical harmonics, characterized by the non-negative integers l with $l \geq |s|$ and integers $-l \leq m \leq l$. Hence, in general, $\sigma^o(u, \theta, \phi) = P(u) \sum_{l=2}^{\infty} \sum_{m=-l}^l {}_sY_{lm}(\theta, \phi)$, where $s = 2$. If the $\bar{\partial}$ and ∂' operators are defined on a round unit 2-sphere, then these ${}_sY_{lm}$ are the known standard spin-weighted spherical harmonics. But as we know when there is a nonzero cosmological constant $\Lambda \neq 0$, these ${}_sY_{lm}$ correspond to those $\bar{\partial}$ and ∂' operators defined on the topological 2-sphere of constant u on $\mathcal{I}$ [the definitions were given in Eqs. (26) and (27)] [15]. We are not attempting here to work out these ${}_sY_{lm}$ on the topological 2-sphere of constant u on $\mathcal{I}$, as that deserves its own formal treatment in an exclusive study. Moreover, so far, we only have the explicit metric for the axisymmetric case [see Eq. (B1)] but not the general one.

Instead, we note that in a multipole expansion of the compact source approximation the quadrupole term corresponds to those where $l = 2$ and the higher multipole terms are those with $l > 2$. Now for *purely quadrupole gravitational waves*, σ^o would have only components with $l = 2$. Since $\delta\sigma^o$ has spin weight $s = 3$, then $\delta\sigma^o = 0$ because it can only have those components with $l \geq s = 3$. We thus have from Eq. (111) the mass-loss formula

$$\frac{dM_B}{du} = -\frac{1}{4\pi} \oint \left(|\dot{\sigma}^o|^2 + \frac{\Lambda}{2} |\delta'\sigma^o|^2 + \frac{2\Lambda^2}{9} |\sigma^o|^4 \right) d^2S, \quad (112)$$

which is manifestly positive definite with an overall negative sign for a universe with a positive cosmological constant, signifying that these purely quadrupole gravitational waves carry positive energy away from the isolated source. This is in agreement with the linearized theory with $\Lambda > 0$, as reported by Ashtekar *et al.* [43].

With higher-multipole terms, however, there would necessarily be negative contributions to the expression for the energy carried away by the radiation [due to the $-|\delta\sigma^o|^2$ term in Eq. (111)]. Of course, what we need for a general σ^o based on physical grounds would be that *at least*

$$\oint \left(|\dot{\sigma}^o|^2 + \frac{\Lambda}{2} |\delta'\sigma^o|^2 - \frac{\Lambda}{6} |\delta\sigma^o|^2 + \frac{2\Lambda^2}{9} |\sigma^o|^4 \right) d^2S \geq 0, \quad (113)$$

where equality here must only be the case with $\sigma^o = 0$. Alternatively, to ensure that the term involving the Gauss curvature K itself is manifestly positive definite, then from Eq. (109), one can impose that

$$|\delta'\sigma^o| \geq |\delta\sigma^o| \quad (114)$$

everywhere or only when integrated over d^2S . Another consideration would be to combine with the other $|\delta'\sigma^o|^2$ term in the mass-loss formula (101) (which coincidentally carries the same factor of $\Lambda/3$ as that of the term with the Gauss curvature) to have this inequality,

$$\sqrt{3}|\delta'\sigma^o| \geq |\delta\sigma^o|, \quad (115)$$

everywhere or only when integrated over d^2S . These provide some bounds that the $l > 2$ components of σ^o would need to satisfy, to guarantee the positive-definiteness of the energy carried away by the outgoing gravitational waves.

V. CONCLUDING REMARKS

In this paper, we have derived the mass-loss formula for an isolated gravitating system due to energy carried away

by gravitational waves in a universe with a cosmological constant, using an integral formula on a hypersurface based on the Nester-Witten identity. The mass-loss formula was obtained by evaluating the integral formula using the asymptotic solutions for asymptotically de Sitter spacetimes near null infinity. Just like deriving the asymptotic solutions with $\Lambda \in \mathbb{R}$ [15] being way more complicated than for $\Lambda = 0$ [20], the calculations involved here were much more tortuous when compared to the asymptotically flat case [26]. Nevertheless, we did eventually arrive at the identical mass-loss formula that was found in Ref. [15]—providing a pleasant consistency check that the Nester-Witten identity and the Bianchi identity return the same answer (as they should).

The Nester-Witten identity is written in the form $dL = S + E$, where dL is a differential of a 2-form L . This provides a natural packaging of the many terms in the mass-loss formula (101), where we have shown that the 3-form dL yields the usual expression for the rate of change of the Bondi mass dM_B/du for any $\Lambda \in \mathbb{R}$. While this is certainly not a physical justification for adopting such a generalization of the Bondi mass to include a cosmological constant, we have backed up the choice of $M_\Lambda = M_B$ for any $\Lambda \in \mathbb{R}$ with a satisfactory result; viz., in a universe with $\Lambda > 0$, the quadrupole gravitational waves would carry away a manifestly positive-definite energy from the isolated source. On top of that, we have also suggested some bounds [Eqs. (113)–(115)] that nonzero higher multipole contributions in σ^o should satisfy (locally or integrated over d^2S) for $\Lambda > 0$. This represents a step forward in the full *nonlinear* theory of general relativity with a positive cosmological constant.

The manifestly positive-definite result, however, is *false* for a universe with $\Lambda < 0$. For instance, if Λ is sufficiently small such that the Λ^2 term is negligible compared to the Λ term and that σ^o does not vary very strongly with u such that $|\dot{\sigma}^o|^2$ is ignorable compared to $\Lambda|\delta'\sigma^o|^2/2$, then we see from Eq. (112) that the energy carried away by quadrupole gravitational waves in an anti-de Sitter-type universe is manifestly negative definite. In such a scenario, perhaps one has to resort to moving that $\Lambda|\delta'\sigma^o|^2/2$ term to be absorbed into a new mass M_Λ , for $\Lambda < 0$, which suggests that we do indeed need to consider correction terms to the Bondi mass when $\Lambda \neq 0$. From another perspective, this may be viewed as a theoretical basis for why a physically realistic universe cannot have a negative cosmological constant because even the lowest-order (quadrupole) gravitational waves could carry away negative energy, as dictated by the full nonlinear theory of general relativity.

APPENDIX A: BEHAVIOR OF EMPTY ASYMPTOTICALLY DE SITTER SPACETIMES

In the asymptotically flat case, the assumption made by Newman and Penrose was only $\Psi_0^o = O(r^{-5})$, together with “uniform smoothness” [17]. With this single condition as their starting point, they were able to deduce the falloffs for everything else, viz., the other dyad components of the Weyl spinor (the peeling property), the spin coefficients, and the unknown functions in the null tetrad. This was possible by harnessing the powerful mathematical result of Coddington and Levinson (see the details in Ref. [17]). Eventually, the freely specifiable physical functions are

$$\Psi_0, \text{ on a null hypersurface } u = \text{constant} \quad (\text{A1})$$

$$\Psi_1^o \text{ and } \text{Re}(\Psi_2^o), \text{ on a } u = \text{constant} \text{ cut of } \mathcal{I} \quad (\text{A2})$$

$$\sigma^o, \text{ on } \mathcal{I}. \quad (\text{A3})$$

Here, u is a retarded null coordinate, and so $u = \text{constant}$ defines an outgoing null hypersurface. The quantities Ψ_1^o , Ψ_2^o , and σ^o are leading-order terms of Ψ_1 , Ψ_2 , and σ , respectively, when expanded in inverse powers of r away from null infinity $\mathcal{I}$, where r is an affine parameter of the outgoing null geodesics. Note that σ^o determines Ψ_3^o and Ψ_4^o (leading-order terms of Ψ_3 and Ψ_4 , respectively).

For our study with $\Lambda \in \mathbb{R}$ in Ref. [15], on the other hand, we shall not restrict ourselves to having a minimal set of assumptions. Instead, we assume from the start that all quantities are expressible as power series in inverse powers of r of sufficiently many orders away from $\mathcal{I}$. This avoids mathematical technicalities in *deriving* the falloffs (which, in our opinion, are unnecessary with regard to getting the *physical* result, and, moreover, they *can* be deduced from admitting a smooth conformal compactifiability of the manifold). Here is our set of assumptions in Ref. [15]:

- (1) The falloffs for the spin coefficients.
- (2) The falloffs for the functions in the null tetrad.
- (3) The Weyl spinor vanishing on $\mathcal{I}$,
- (4) The stipulation that $\Psi_0 = \Psi_0^o r^{-5} + O(r^{-6})$.

Incidentally, it was realized much later that one does not need to assume $\Psi_0 = O(r^{-5})$ when $\Lambda \neq 0$, as this can be derived from the other assumptions (see Ref. [29]). Our ansatz for deriving the asymptotic solutions to the Newman-Penrose (NP) equations with $\Lambda \in \mathbb{R}$ are made by studying the Schwarzschild-de Sitter spacetime. One can then calculate through the 38 NP equations to find that they are all consistent (as far as the relevant orders that we have checked), and also that these asymptotic solutions reduce exactly to the ones for $\Lambda = 0$ as found in Ref. [32]. The peeling property of the Weyl (and Maxwell) spinor(s) with Λ similarly follows from the same set of Bianchi identities (Maxwell equations) as in the $\Lambda = 0$ case. For the extension to include Maxwell fields in Ref. [16], we correspondingly assume that the Maxwell spinor vanishes on $\mathcal{I}$ and $\phi_0 = O(r^{-3})$ (but see Ref. [29] on how this falloff

for ϕ_0 may not be required as an additional stipulation when $\Lambda \neq 0$). The freely specifiable physical functions with $\Lambda \neq 0$ are the same as the $\Lambda = 0$ setup.

While our study and our ansatz are purely within the physical spacetime, they are all consistent with the falloffs that were worked out by Szabados and Tod [30]. By assuming a smooth conformal compactifiability, they derived the falloffs for the spin coefficients and the metric. One can carry out the appropriate boost transformation and null rotation to reconcile their null tetrad with ours here, to find that our set of assumptions agrees with their results—including several gauge-fixing choices that lead to the vanishing of certain terms.

APPENDIX B: PROOF THAT THE AREA ELEMENT OF THE TOPOLOGICAL 2-SPHERES OF CONSTANT u ON $\mathcal{I}$ IS INDEPENDENT OF u

We give a proof that the area of the topological 2-spheres of constant u on $\mathcal{I}$ is the same as that of a round unit 2-sphere. Before dealing with the general case, we see that for the axisymmetric case the metric is [15]

$$g_{axi} = e^{2\Lambda f(u,\theta)} d\theta^2 + e^{-2\Lambda f(u,\theta)} \sin^2 \theta d\phi^2, \quad (\text{B1})$$

where $3f(u, \theta) = \int \sigma^o(u, \theta) du$. One can get the area element by calculating the square root of the determinant to find that $d^2 S = \sin \theta d\theta d\phi$, which is just the usual area element of a round unit 2-sphere. This area element is independent of u , and the total area is just $A = \oint d^2 S = \int_0^{2\pi} \int_0^\pi \sin \theta d\theta d\phi = 4\pi$.

For the general case, however, we do not have the explicit expression for the metric. Anyway, the area element for a topological 2-sphere of constant u on $\mathcal{I}$ is

$$d^2 S = \frac{1}{r^2} d^2 A, \text{ in the limit where } r \rightarrow \infty, \quad (\text{B2})$$

where $d^2 A = -im_a \wedge \bar{m}_b$. In other words, $d^2 A$ is the area element for the surfaces of constant u and r . When expanded in inverse powers of r , its leading-order term carries a factor of r^2 , i.e., $d^2 A = r^2 d^2 S + O(r)$. Division by r^2 and taking $r \rightarrow \infty$ would give the required area element on $\mathcal{I}$, which is $d^2 S$.

Let us now evaluate the u derivative of this area element $d^2 S$. If one uses the Newman-Unti null tetrad that was employed in Refs. [15,16], then consider $\vec{Z} = \vec{n}_{\text{Saw}} - U \vec{l}_{\text{Saw}} = \vec{\partial}_u + X^\mu \vec{\partial}_\mu$ [47]. We can calculate the u derivative of $d^2 S$ by taking the Lie derivative of $d^2 S$ along $\vec{\partial}_u$.

Note that $d^2 S$ has no r dependence. The Lie derivative of $d^2 S$ along $X^\mu \vec{\partial}_\mu$ essentially unravels into taking derivatives of $d^2 S$ with respect to the two angles (or the two coordinates intrinsic to this 2-surface). The factor of $X^\mu = O(r^{-3})$ [Eq. (21)] would imply that in the limit where $r \rightarrow \infty$ this would be zero.

Therefore, we are left with working out the Lie derivative of d^2S along $\vec{Z}$. With a calculation similar to that in Sec. III B,

$$\frac{\partial}{\partial u}(d^2S) = \mathcal{L}_{\vec{Z}}(d^2S) \quad (\text{B3})$$

$$= \frac{1}{r^2} \mathcal{L}_{\vec{Z}}(d^2A), \text{ in the limit where } r \rightarrow \infty \quad (\text{B4})$$

$$= \frac{2}{r^2} \text{Re}(U\rho_{\text{Saw}} - \rho'_{\text{Saw}})d^2A, \text{ in the limit where } r \rightarrow \infty \quad (\text{B5})$$

$$= 2\text{Re}(U\rho_{\text{Saw}} - \rho'_{\text{Saw}})d^2S, \text{ in the limit where } r \rightarrow \infty. \quad (\text{B6})$$

Explicit calculations show that $2\text{Re}(U\rho_{\text{Saw}} - \rho'_{\text{Saw}}) = O(r^{-2})$ [48], so

$$\frac{\partial}{\partial u}(d^2S) = 0, \quad (\text{B7})$$

i.e., the area element of the topological 2-sphere of constant u on $\mathcal{I}$ is independent of u , and so the total area of such a topological 2-sphere is the same as that of the round unit 2-sphere, which is 4π .

[18] Reference [16] is an extension of Ref. [15] to include Maxwell fields. The case with purely Maxwell fields is clear: the mass-loss formula for electromagnetic (EM) radiation says that outgoing EM waves strictly decrease the total mass energy of the source, while incoming EM waves from elsewhere strictly increase its total mass energy. The gravitational case, on the other hand, is not as straightforward. See also Ref. [19] for a concise summary of the results found in Refs. [15,16].

[21] Note that the term involving the u derivative of the area element appearing in Eq. (126) in Ref. [15] is zero, as pointed out in footnote s of Ref. [14]. We give an explicit proof in Appendix B. Incidentally, while the ansatz for the falloffs of various quantities used in Ref. [15] were guessed based on studying the form of the Schwarzschild-de Sitter spacetime (and subsequently shown to be consistent throughout the calculations involving all 38 Newman-Penrose equations), these falloffs all agree with the corresponding results from assuming a smooth conformal compactifiability [30].
[22] In solving the 38 Newman-Penrose equations in Ref. [15], the expression for K arises from the spin coefficient equation involving $\delta\alpha$ and $\delta'\alpha'$. In general, K equals $2\Theta(\theta, \phi)$ plus those new terms involving Λ and σ'' in Eq. (25). Here, $\Theta(\theta, \phi)$ is a free function of the two angular coordinates intrinsic to the 2-surfaces of constant u on $\mathcal{I}$, which is introduced as a “constant of integration.” As was stipulated in Ref. [15], the choice of setting $\Theta(\theta, \phi)$ to $1/2$ implies that $K = 1$ so that this is associated with a round unit 2-sphere, if Λ or σ'' is zero. Hence, the presence of σ'' and Λ would induce warpings on the round unit 2-sphere, resulting in a nonconformally flat $\mathcal{I}$ as one finds that the Cotton tensor of $\mathcal{I}$ becomes nonzero.

- [24] A need for corrections to the mass M_Λ is particularly compelling for the $\Lambda < 0$ case, in which the term involving $\Lambda|\delta'\sigma^\sigma|^2$ in Eq. (2) is negative definite.
- [25] We will find that the $\Lambda < 0$ case would not give a manifestly positive-definite expression for the energy carried away by gravitational waves because the terms with a factor of Λ would then have the opposite sign.

- [33] J. Frauendiener (private communication).
- [34] Note that our $\mathcal{R}$ here is twice that in Ref. [26]. This is so our $\mathcal{R}$ would be twice the Gauss curvature. In Ref. [26], the $\mathcal{R}$ there is four times the Gauss curvature.
- [35] The s derivative of the area element d^2A can be evaluated once a choice of $\vec{Z}$ is made, to end up with an expression analogous to Eq. (76) below in terms of Z and Z' . In that case, since ϕ and ϕ' are arbitrary, we see that we get equations for the integrands themselves without having to carry out the integration on the 2-surface S_s for some fixed s . We should expect that the resulting differential equations are equivalent to (some of) the Bianchi identities—but one should carefully revisit the paper in Ref. [26] to go through the entire derivation right from the start. As the purpose of this paper is to study the Bondi mass, we do not go into that discussion here but instead carry on with the integrated formulas.
- [36] The null tetrad vectors and spin coefficients taken directly from Refs. [15,16] are denoted with a subscript “Saw.” Then, the ones converted via a null rotation around $\vec{l}$ to be used for evaluating Eq. (15) will have no subscript tagged to them. Incidentally, the Einstein summation convention is assumed for μ , over the two angular coordinates intrinsic to the topological 2-spheres S_s .
- [37] Later, in Sec. IV in which we derive an identity involving K [that appears in the mass-loss formula (101)] in terms of only the δ and δ' of σ^σ [see Eq. (109)], we see that $\Theta(x^\mu)$ plays no role and does not affect the mass-loss formula. Therefore, $\Theta(x^\mu)$ does not carry any physical significance with regard to the mass-loss formula, and so we set $\Theta(x^\mu) = 1$.
- [38] The indices on the right-hand side are inserted to keep track of the 1-forms m_a and $\bar{m}_b$, especially in the calculations that follow.
- [39] These higher-order terms of $\mathcal{R}$ may be derived using the spin coefficient equation involving the δ and δ' derivatives of α and α' [27]. This gives $\mathcal{R}_3^\sigma = 4\text{Re}(\delta^2\bar{\sigma}^\sigma)$ and $\mathcal{R}_4^\sigma = 2K|\sigma^\sigma|^2 - 4|\delta'\sigma^\sigma|^2 - 4\text{Re}(\sigma^\sigma\delta'\delta\bar{\sigma}^\sigma)$, in agreement with the results found in Eqs. (85) and (86) using the first integral formula.

- [41] Note that with this identity involving K we did not actually need the explicit expression for K given in Eq. (25); i.e., the mass-loss formula is independent of the choice of $\Theta(x^\mu)$.

- [47] On the other hand, if one uses the null tetrad that Frauendiener employed [26], which is the one taken in this paper to evaluate his integral formula, then consider $\vec{Z} = \vec{n} - (U - \omega\bar{\omega})\vec{l} = \vec{\partial}_u + (X^\mu - 2\text{Re}(\bar{\omega}\xi^\mu))\vec{\partial}_\mu$. Either way, one gets the same result—see the next footnote.
- [48] Similarly, $2\text{Re}((U - \omega\bar{\omega})\rho - \rho') = O(r^{-2})$, which is what appears in the corresponding calculation with the other null tetrad.
