Abstract: Chemo-photothermal nanotheranostics has the advantage of synergistic therapeutic effect, providing opportunities for optimized cancer therapy. However, current chemo-photothermal nanotheranostic systems generally comprise more than three components, encountering the potential issues of unstable nanostructures and unexpected conflicts in optical and biophysical properties among different components. We herein synthesize an amphiphilic semiconducting polymer (PEG-PCB) and utilize it as a multifunctional nanocarrier to simplify chemo-photothermal nanotheranostics. PEG-PCB has a semiconducting backbone that not only serves as the diagnostic component for near-infrared (NIR) fluorescence and photoacoustic (PA) imaging, but also acts as the therapeutic agent for photothermal therapy. In addition, the hydrophobic backbone of PEG-PCB provides strong hydrophobic and π-π interactions with the aromatic anticancer drug such as doxorubicin for drug encapsulation and delivery. Such a trifunctionality of PEG-PCB eventually results in a greatly simplified nanotheranostic system with only two components but multimodal imaging and therapeutic capacities, permitting effective NIR fluorescence/PA imaging guided chemo-photothermal therapy of cancer in living

mice. Our study thus provides a molecular engineering approach to integrate essential properties into one polymer for multimodal nanotheranostics.

1. Introduction

Development of nanotechnology in the past few decades has stimulated the emergence of nanotheranostics for simultaneous diagnosis and therapeutics of diseases.[1] Nanotheranostics has the ability to monitor disease status before and during treatment, providing optimized therapeutic window and personalized treatment strategy.[2-4] Recently, chemo-phototherapy has been regarded as a promising treatment for solid tumors.[5-7] In particular, chemo-photothermal nanotheranostics integrating anticancer drug with thermal ablation not only overcomes the multidrug resistance of conventional chemotherapy, but also brings in synergistic therapeutic effect to improve therapeutic outcome.[8-10] Such combined nanotheranostics thus has the potential advantages of reduced risk of cancer recurrence and minimized side effects relative to monotherapy.[11]

Current chemo-photothermal nanotheranostic systems often use fluorescence for diagnosis mainly due to its low cost and high sensitivity for whole-body imaging.[12, 13] However, fluorescence imaging often encounters the issue of shallow penetration depth as a result of tissue autofluorescence and light scattering.[14, 15] Thus, photoacoustic (PA) imaging that breaks the optical diffusion limit has recently been integrated into chemo-photothermal nanotheranostics, which has the advantage of increased imaging depth theoretically up to 7 cm.[16-21] Till now, numerous theranostic nanoagents have been exploited for chemo-photothermal therapy, such as 2D nanomaterials,[22-25] gold nanostructures,[26, 27] carbon-metal composites,[28] small-molecule dye loaded nanoparticles,[29] and so on.[30] However, because most chemo-photothermal nanotheranostic systems comprise more than three components (imaging agents, drug, photothermal agents and encapsulating polymers et al.),

clinical translation of these nanotheranostics faces many challenges, which include complex and unstable nanostructure as well as unexpected conflicts in optical and biophysical properties among different components. As a result, rational design of nanotheranostics with minimal components and simple nanostructure is highly desired.

Semiconducting polymer nanoparticles (SPNs) have been recently transformed to organic theranostic nanoagents owning to their higher absorption and photothermal conversion efficiencies in near-infrared (NIR) region as compared with other inorganic nanoparticles such as carbon nanotubes and gold nanorods.[31-37] Because their optical and photothermal properties come from long π-electron delocalized backbones, SPNs generally possess better photostability than small-molecule dyes.[38] Recently, we have applied SPNs for fluorescence and PA imaging applications as well as photothermal therapy and control of neural activity.[39-47] Despite their promise in nanotheranostics, SPN-based chemo-photothermal systems are rarely developed,[48-50] which are complicated and composed of more than three components.
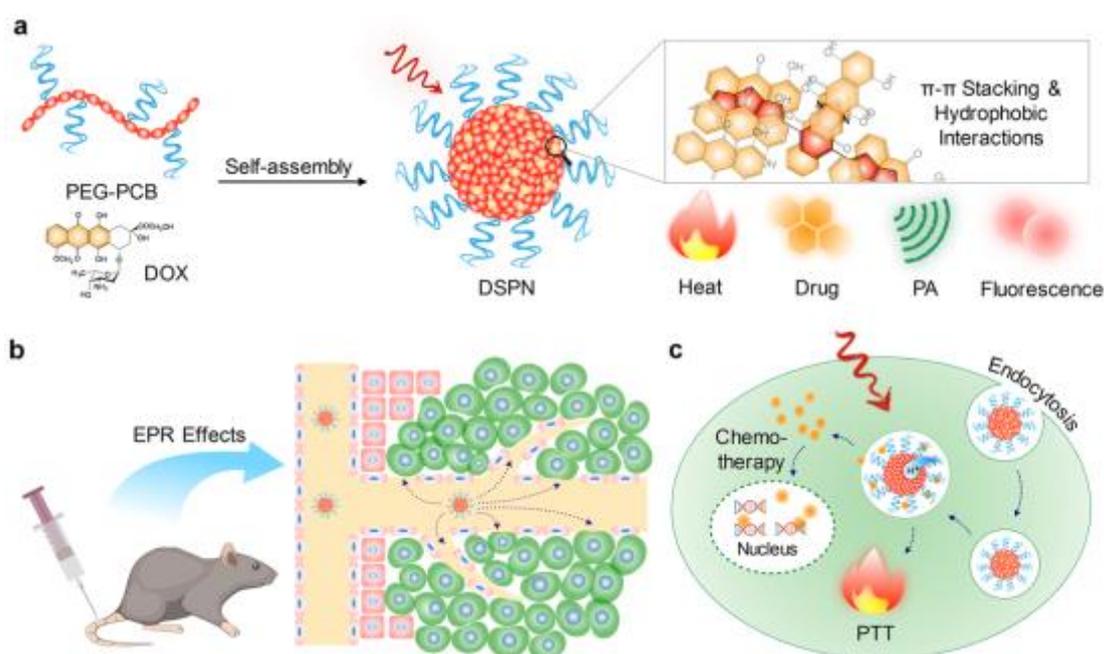

Scheme 1. (a) Schematic illustration of preparation of DSPN. (b) and (c) Synergistic effect of chemotherapy and PTT of cancer by DSPN.

In this study, we report a simple dual-component nanotheranostic system based on SPNs for NIR fluorescence/PA imaging guided chemo-photothermal therapy (Scheme 1a). Such a nanotheranostic design takes advantage of an amphiphilic poly(ethylene glycol) (PEG) grafted poly(cyclopentadithiophene-*alt*-benzothiadiazole) (PEG-PCB), which is a highly integrated multifunctional component that self-assembles into homogenous nanoparticles in aqueous solution. As a result of π-conjugated backbone, PEG-PCB not only serves as the diagnostic component for NIR fluorescence and PA imaging, but also acts as the photothermal agent by efficiently converting photon energy into heat. In addition, the hydrophobic π-conjugated backbone of PEG-PCB provides strong hydrophobic and π-π interactions with the aromatic anticancer drug such as doxorubicin (DOX) for drug encapsulation and delivery. Such a unique trifunctional feature of PEG-PCB leads to the greatly simplified nanotheranostic system with only dual components but multimodal imaging and therapeutic capacities. In the following, we first describe the synthesis and characterization of PEG-PCB and drug-loaded PEG-PCB (DSPN), followed by *in vitro* studies of the cellular internalization and chemo-photothermal therapeutic efficacy. At last, the proof-of-concept application of theranostic DSPN in fluorescence/PA imaging guided chemo-photothermal therapy of tumor in living mice is demonstrated.

2. Results and Discussion

The amphiphilic PEG-PCB was synthesized via a grafting-on approach (Fig. 1a). Monomers 1 and 2 were copolymerized via Suzuki polycondensation reaction to afford the polymer with bromide side groups (PCB-Br). The bromide groups were converted to azide, allowing for copper(I)-catalyzed azide-alkyne click reaction (CuAAC) to graft hydrophilic PEG chains onto highly hydrophobic polymer backbones. The resulted polymer (PEG-PCB) could be directly dissolved water and self-assemble into nanoparticles. Drug-loaded nanoparticles (DSPNs) were prepared via nanoprecipitation of deprotonated DOX and PEG-PCB under controlled pH

condition, followed by dialysis to remove excess free DOX. The solutions of nanoparticles kept translucent before and after drug loading (Fig. 1b), while the color of solutions changed from cyan to crimson owning to the incorporation of DOX. Dynamic light scattering (DLS) revealed the diameter increased from 40 nm for PEG-PCB to 100 nm for DSPN with the highest drug loading capacity (LC = 20.3%, W_{DOX}/W_{PCB} = 5, termed as $DSPN_5$) (Fig. 1c). Spherical morphology was observed for both PEG-PCB and $DSPN_5$ by transmission electron microscopy (TEM) (Fig. 1d). In addition, no precipitation or obvious change in diameter was observed for both PEG-PCB and $DSPN_5$ after storage in $1 \times$ PBS (pH = 7.4) for two months, suggesting their excellent aqueous stability (Fig. S4, supporting information).

(i) $Pd(PPh_3)_4$, K_2CO_3, methyltrioctylammonium chloride, Toluene/H_2O; (ii) NaN_3; (iii) mPEG-alkyne, CuBr, PMDETA, THF. (b) Photographs of PEG-PCB and $DSPN_5$ solution. (PCB 10 μg/ml, DOX 50 μg/ml). (c) Size distribution of PEG-PCB and $DSPN_5$ by DLS. (d) TEM images of PEG-PCB (left) and $DSPN_5$ (right).

Optical properties of DSPN were studied and compared with PEG-PCB under physiological conditions. PEG-PCB had one absorption peak at 670 nm assigned to the absorbing PCB (Fig.

2a), while DSPN showed an additional absorption peak at 500 nm attributed to DOX. The absorbance of DSPN at 500 nm gradually increased with the doping ratio of DOX. Although the fluorescence spectra of SPN and DSPN had the emission maximum at 825 nm (Fig. 2b), the fluorescence was quenched after the loading of DOX. Compared with PEG-PCB, a 75% decrease of fluorescence intensity at 825 nm was observed for DSPN5. Such fluorescence quenching should be attributed to the charge transfer between the π-conjugated polymer backbones and the anthraquinone part of DOX. Furthermore, both SPN and DSPN5 emitted PA signals ranging from 680 to 900 nm with the peak signal at 680 nm (Fig. 2c), correlated well with their absorption spectra (Fig. 2a). As the fluorescence of DSPN5 was quenched and that part of energy was converted into heat,[39] the PA amplitudes of DSPN5 were slightly higher than those of PEG-PCB.

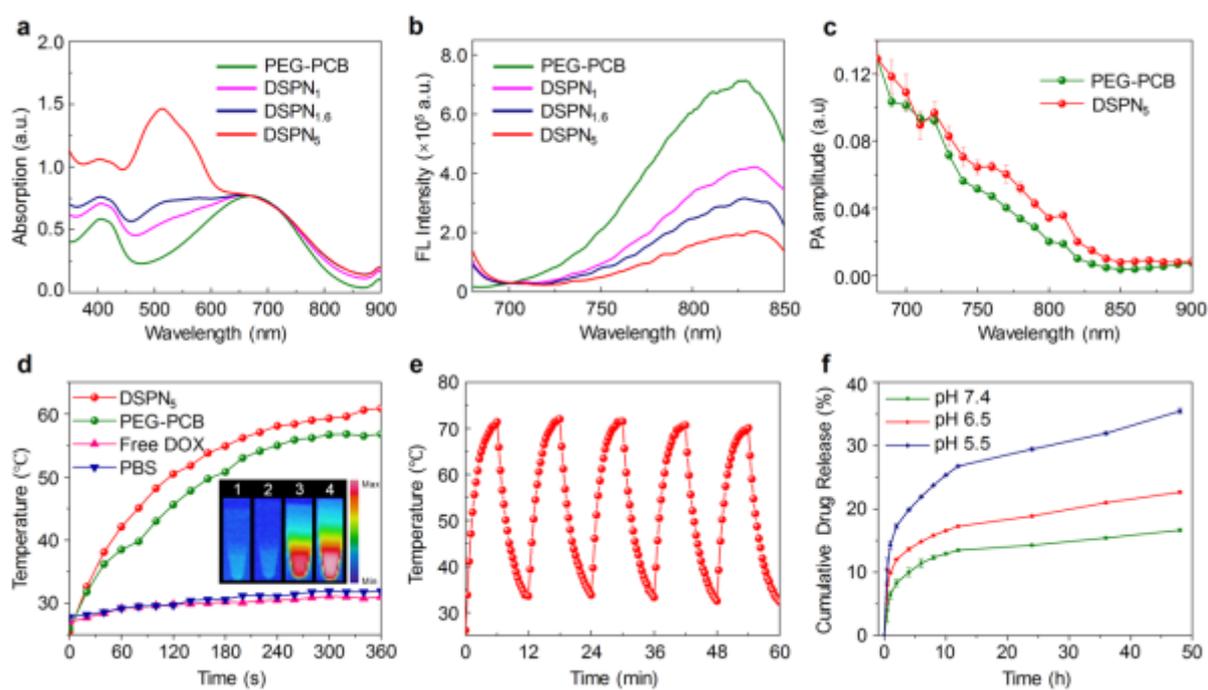

Fig. 2. *In vitro* optical, PA, photothermal, and drug release properties of PEG-PCB and DSPN in $1 \times$ PBS. (a) UV-Vis-NIR absorption and (b) Fluorescence spectra of PEG-PCB and DSPN with different loading ratio (W_{DOX}/W_{PCB} = 1, 1.6, and 5 for DSPN1, DSPN1.6, and DSPN5, respectively). Excitation wavelength, 670 nm. (c) PA spectra of PEG-PCB (PCB, 100 μg/ml)

and DSPN$_5$ (PCB, 100 µg/ml; DOX, 500 µg/ml). (d) Photothermal profiles, thermal images of PBS (1), free DOX (2) (DOX, 50 µg/ml), PEG-PCB (3) (PCB, 10 µg/ml), and DSPN$_5$ (4) (PCB, 10 µg/ml; DOX, 50 µg/ml) under irradiation of 808 nm laser (laser intensity, 1 W/cm^2). (e) Stability study of DSPN$_5$ under the photothermal heating and natural cooling cycles (laser intensity, 1 W/cm^2; PCB, 18 µg/ml; DOX, 90 µg/ml). (f) Cumulative drug release of DSPN$_5$ under different pH conditions at 37 ℃ (PCB, 0.2 mg/ml; DOX, 1 mg/ml). Error bars indicate standard deviations of 3 separate measurements.

Photothermal properties of PEG-PCB and DSPN$_5$ were subsequently investigated and compared. Under laser irradiation at 808 nm with the power intensity of 1 W/cm^2, the solution temperatures for both PEG-PCB and DSPN$_5$ gradually increased, which was not observed for PBS and free DOX solutions (Fig. 2d). After continuous laser irradiation for 6 min, the solution temperatures of both PEG-PCB and DSPN$_5$ reached a plateau. At this time point, the solution temperature of DSPN$_5$ (60.9 ℃) was about 4.1 ℃ higher than that of PEG-PCB (56.8 ℃). Such slightly enhanced maximum photothermal temperature for DSPN$_5$ should be attributed to the additional heat generated by DSPN$_5$ as a result of quenched fluorescence. The reversible heating-cooling operation showed that the maximum solution temperatures of DSPN$_5$ retained almost unchanged throughout at least 5 heating-cooling cycles, indicating its good photostability (Fig. 2e). Besides, the photothermal conversion efficiency of DSPN$_5$ at 808 nm was calculated to be 30.8% according to the previously reported procedure.[40] In addition, drug release property of DSPN$_5$ was studied by dialysis of DSPN$_5$ in 1 × PBS buffer under different pH conditions (pH = 5.5, 6.5, and 7.4) at 37 ℃ (Fig. 2f). After 48 h of dialysis, ~35.5% of DOX was released from DSPN$_5$ at pH 5.5, followed by 22.7% at pH 6.5 and 16.7% at pH 7.4. This pH-dependent drug release behavior should be attributed to the protonation of amine group of DOX under acidic conditions, which enhanced its hydrophilicity and facilitated its

escape from the hydrophobic core of DSPN$_5$. These results indicated that DSPN$_5$ had suitable photothermal and drug release properties for chemo-photothermal therapy.

To study the *in vitro* cellular uptake and drug release properties of nanoparticles, confocal laser scanning microscopy (CLSM) was conducted on murine breast cancer cells (4T1). After incubation with free DOX, PEG-PCB, or DSPN$_5$ for 12 h, cells were washed by PBS buffer and then stained with nuclear indicator 4',6-diamidino-2-phenylindole (DAPI, depicted in blue). NIR fluorescence (depicted in red) was observed for PEG-PCB or DSPN$_5$ treated cells (Fig. 3a), showing the cellular internalization of both nanoparticles. Moreover, the fluorescence of DOX was detected for DSPN$_5$ treated cells. Although the strongest signal from DOX was observed in cytoplasm, there was a signal overlap between the fluorescence of DOX and of DAPI (Fig. 3a). This data proved that DOX was released from DSPN$_5$ and diffused to nuclei, probably attributed to the protonation of amine group of DOX under acidic conditions in lysosomes (Scheme 1c), which enhanced the hydrophilicity of DOX and facilitated its escape from the hydrophobic core of DSPN$_5$.

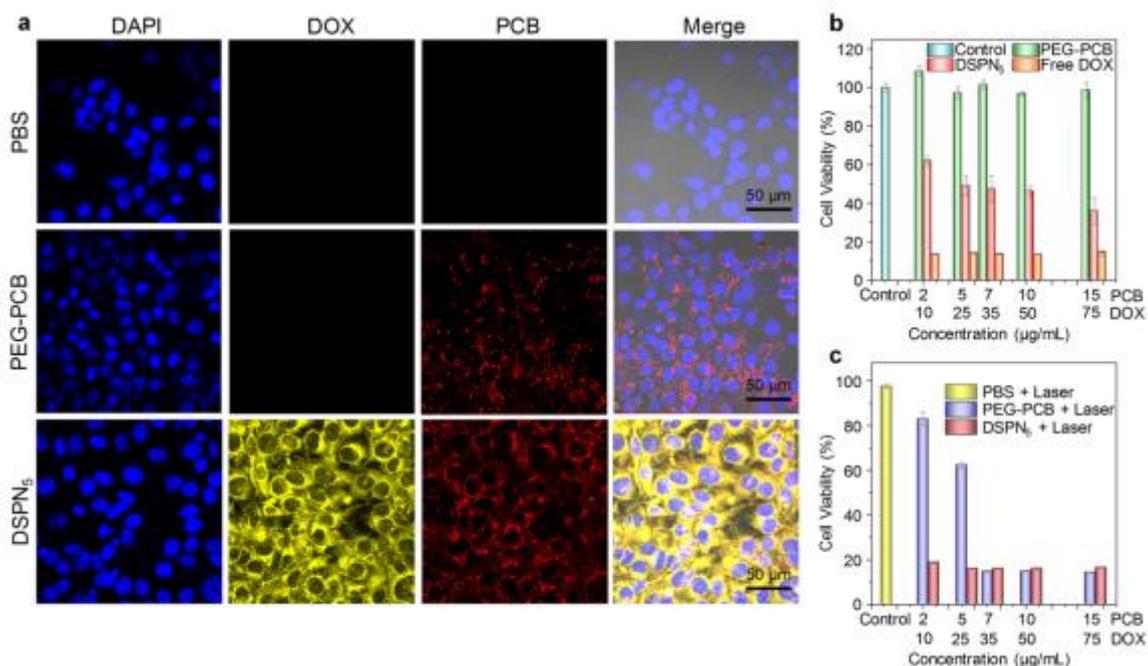

Fig. 3. *In vitro* characterization of combination therapy by DSPN$_5$. (a) Confocal fluorescence images of 4T1 cells after incubation with PBS, PEG-PCB (PCB, 10 μg/ml), and DSPN$_5$ (PCB,

10 μg/ml; DOX, 50 μg/ml) for 12 h. (b) Cell viabilities of 4T1 cells after incubation with PBS, free DOX, PEG-PCB, and DSPN$_5$ with different concentrations. (c) Cell viabilities of 4T1 cells after incubation with PBS, PEG-PCB, and DSPN$_5$ with different concentrations after laser irradiation for 6 min (laser intensity, 1 W/cm^2). Error bars indicate standard deviations of 3 separate measurements.

In vitro therapeutic efficacy of combination therapy vs monotherapy was evaluated and compared by cell viability tests. Without laser irradiation, PEG-PCB showed negligible toxicity to 4T1 cells while DSPN$_5$ had a significantly lower cell viability as compared with PEG-PCB at each concentration (Fig. 3b). This verified the increased cytotoxicity of DSPN$_5$ than PEG-PCB due to the presence of DOX, although the cytotoxicity was weaker than that of free DOX probably owning to the controlled release of DOX from DSPN$_5$ which somehow compromised the therapeutic efficacy (Fig. 3b). After irradiation of 808 nm laser for 6 min, cells incubated with PEG-PCB or DSPN$_5$ showed obvious decrease in viability at each concentration as compared to those without laser irradiation (Fig. 3c vs 3b), indicating the enhanced cytotoxicity owning to PTT. It was noted that DSPN$_5$ mediated PTT treatment caused the highest cytotoxicity among all the treatments. In particular, at the concentration of 2 μg/mL for PCB and 10 μg/mL for DOX, cell viability after DSPN$_5$ mediated PTT treatment was about 19%, which was much lower than that by DSPN$_5$ alone (62%) and SPN-mediated PTT (83%). Furthermore, PEG-PCB was only able to achieve similar cytotoxicity at a much higher concentration (7 μg/mL of PCB) (Fig. 3c), and DSPN$_5$ without PTT treatment was insufficient to cause such high cytotoxicity within experimental range (Fig. 3b). These results demonstrated the overall enhanced therapeutic efficacy of combination therapy relative to monotherapy, highlighting the synergistic antitumor effect of DSPN$_5$ for cancer therapy.

Fig. 4. *In vivo* dual-modal NIR fluorescence/PA tumor imaging. (a) Fluorescence images of living mice bearing xenograft 4T1 tumors at 0, 4, 6, 8 and 24 h after tail-vein injection of PEG-PCB (PCB 30 μg per mouse) or DSPN$_5$ (PCB, 30 μg; DOX, 150 μg per mouse) (n=3). (b) Fluorescence intensities extracted from tumor regions as a function of time after systemic administration of PEG-PCB or DSPN$_5$ (n=3). (c) *Ex vivo* quantification of average fluorescence intensity of major organs of mice after systemic administration of PEG-PCB or DSPN$_5$ for 24 h (n = 3). (d) Representative 3D images of tumor on a living mouse at 0 and 8 h after injection of DSPN$_5$ (PCB, 30 μg; DOX, 150 μg per mouse) (n=3). (e) *In vivo* real-time PA spectra extracted from tumor regions in living mice after systemic administration of DSPN$_5$ or saline for 24 h (n=3).

Dual-modal NIR fluorescence/PA imaging were conducted on living mice bearing 4T1 xenograft tumors to identify the optimum therapeutic window. After systemic administration of PEG-PCB or DSPN$_5$ *via* tail vein injection, both fluorescence and PA signals of living mice were continually monitored. As shown in Fig. 4a and b, the fluorescence intensities from the

10

tumor region for both PEG-PCB and DSPN$_5$ treated mice increased over time and reached the maximum at 6 h post-injection. At this time point, the fluorescence intensity of tumor region on DSPN$_5$ treated mice was 0.87-fold of that on PEG-PCB treated mice. The lower fluorescence intensity for DSPN$_5$ treated mice should be attributed to the quenching of fluorescence by DOX (Fig. 2b). Moreover, the decreased accumulation of DSPN$_5$ in tumors as indicated by the lower tumor-to-liver intensity ratio (TLR) of DSPN$_5$ vs PEG-PCB (1.0 vs 1.6) treated mice should be responsible (Fig. S6, supporting information), which could be ascribed to the relatively larger size of DSPN$_5$ than PEG-PCB. Similarly, the PA signal of tumor region reached the maximum at 8 h post-injection of DSPN (Fig. S7 and S8, supporting information). At this time point, the PA amplitude of tumor region in DSPN$_5$ treated mice was 3.8-fold higher than that of tumor background, which was consistent with the fluorescence imaging. As a result of the high optical contrast and spatial resolution of PA technique, 3D PA image after injection of DSPN$_5$ was able to clearly delineate the tumor region of living mouse (Fig. 4d). Real-time *in vivo* PA spectrum extracted from tumor regions of DSPN$_5$ treated mice (Fig. 4e) resembled that of DSPN$_5$ in aqueous solution (Fig. 2c), confirming that the PA signal resulted from the accumulation nanoparticles. *Ex vivo* data further revealed that liver had the strongest fluorescence for both PEG-PCB and DSPN$_5$ treated mice, followed by tumor, and other organs (Fig. 4c and Fig. S5, supporting information). No obvious change was measured between the biodistribution of PEG-PCB and DSPN$_5$ treated mice, probably due to their similar PEG surface. These in vivo and ex vivo imaging data proved that both PEG-PCB and DSPN$_5$ could passively target the tumors in living mice *via* enhanced permeability and retention (EPR) effect due to their idea sizes (within 100 nm) and PEGylated surface (Scheme 1b).
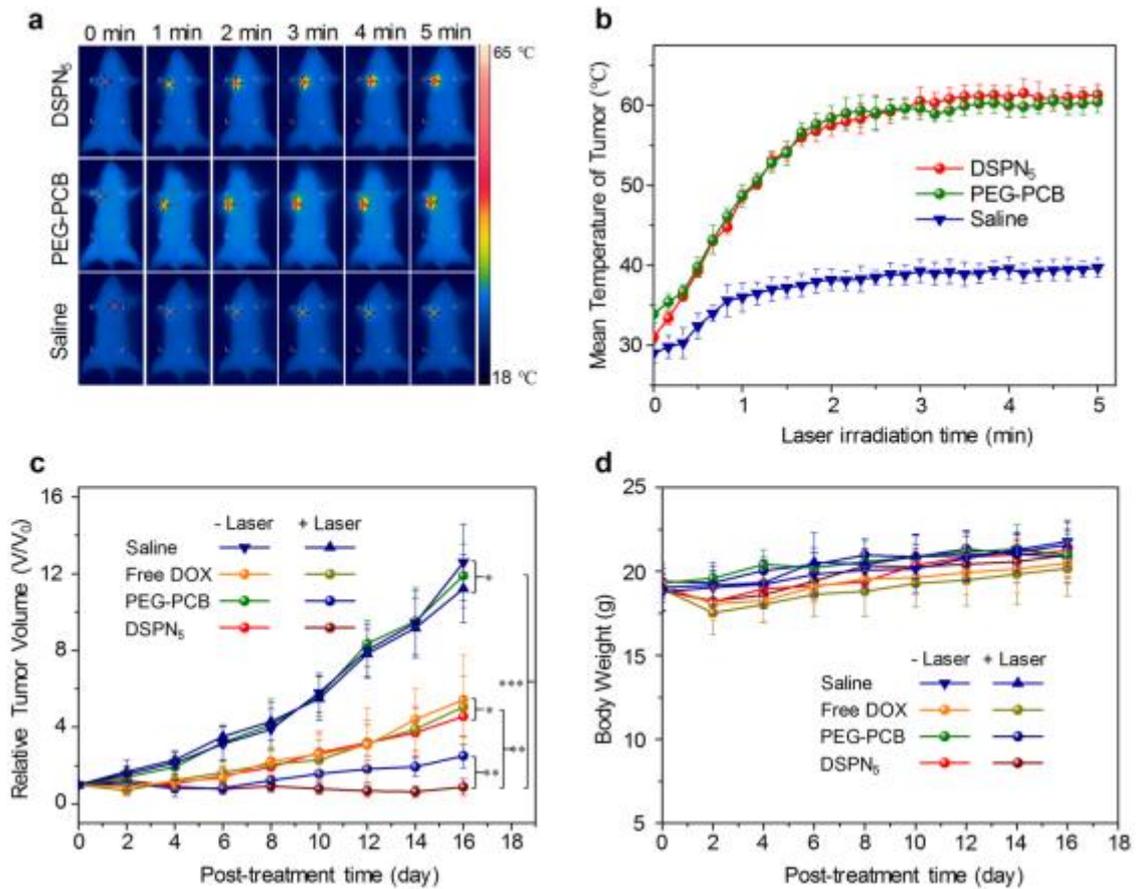

Fig. 5. *In vivo* combination therapy. (a) IR thermal images of 4T1-bearing mice under 808 nm laser irradiation (0.3 W/cm^2) at 6 h after systemic administration of saline, PEG-PCB (PCB 30 μg per mouse), or DSPN$_5$ (PCB, 30 μg; DOX, 150 μg per mouse) (n=3). (b) Mean tumor temperature as a function of laser irradiation time at 8 h post-injection of DSPN$_5$, PEG-PCB, or saline (n=3). (c) Tumor growth curves and (d) body weight data of different groups of mice after systemic administration of DSPN$_5$, PEG-PCB, or saline with and without laser irradiation (n = 3). (*$p > 0.05$, **$p < 0.05$, ***$p < 0.01$).

Therapeutic efficacy of PEG-PCB and DSPN$_5$ was tested and compared in 4T1 xenograft tumor mouse model. According to the *in vivo* imaging data, PTT treatment was applied at 6 h post-injection of PEG-PCB or DSPN$_5$ when the accumulation of nanoparticles in the tumor reached the maximum. After systemic administration of DSPN$_5$, PEG-PCB, or saline for 6 h, the tumor region in living mice was irradiated by 808 nm laser with the power intensity of 0.3

W/cm^2 (the maximum exposure limit of skin to laser irradiation at 808 nm) for 5 min. Upon laser irradiation, the temperature of tumor region for DSPN$_5$ or PEG-PCB treated mice gradually increased (Fig. 5a, b), which was significantly higher than that for saline treated group at all time points. The temperature of tumor for PEG-PCB or DSPN$_5$ treated mice reached a plateau after laser irradiation for 2 min, and the mean temperature of tumor for SPN (59.6 ℃) or DSPN$_5$ treated mice (60.5 ℃) was about 1.5-fold of that for saline treated mice (39.3 ℃). Despite the higher in vitro photothermal maximum temperature of DSPN$_5$ relative to PEG-PCB (Fig. 2d), no significant difference of tumor temperature was observed between PEG-PCB and DSPN$_5$ treated mice, which might be attributed to the reduced accumulation of DSPN$_5$ in tumor region as indicated by the lower TLR of DSPN$_5$ than PEG-PCB (Fig. S6, supporting information).

To evaluate and compare the antitumor effect of PEG-PCB and DSPN$_5$, the volumes of tumors in living mice were continuously measured for 16 days (Fig. 5c). Without laser irradiation, tumors in DSPN$_5$ treated mice grew much slower than those for saline or PEG-PCB treated mice, indicating the certain level of antitumor effect of DSPN$_5$ by chemotherapy. With laser irradiation, PEG-PCB inhibited the growth of tumors for the first 6 days while failed at later time points, suggesting the limited antitumor effect of PEG-PCB mediated PTT. In comparison, only DSPN$_5$ mediated PTT completely inhibited the growth of tumors throughout the experimental period. The superior antitumor capability of DSPN$_5$ over PEG-PCB should be attributed to the synergistic effect resulted from the combination of chemotherapy and PTT. No significant weight loss was observed for all groups (Fig. 5d), indicating the safety of all treatments to mice.
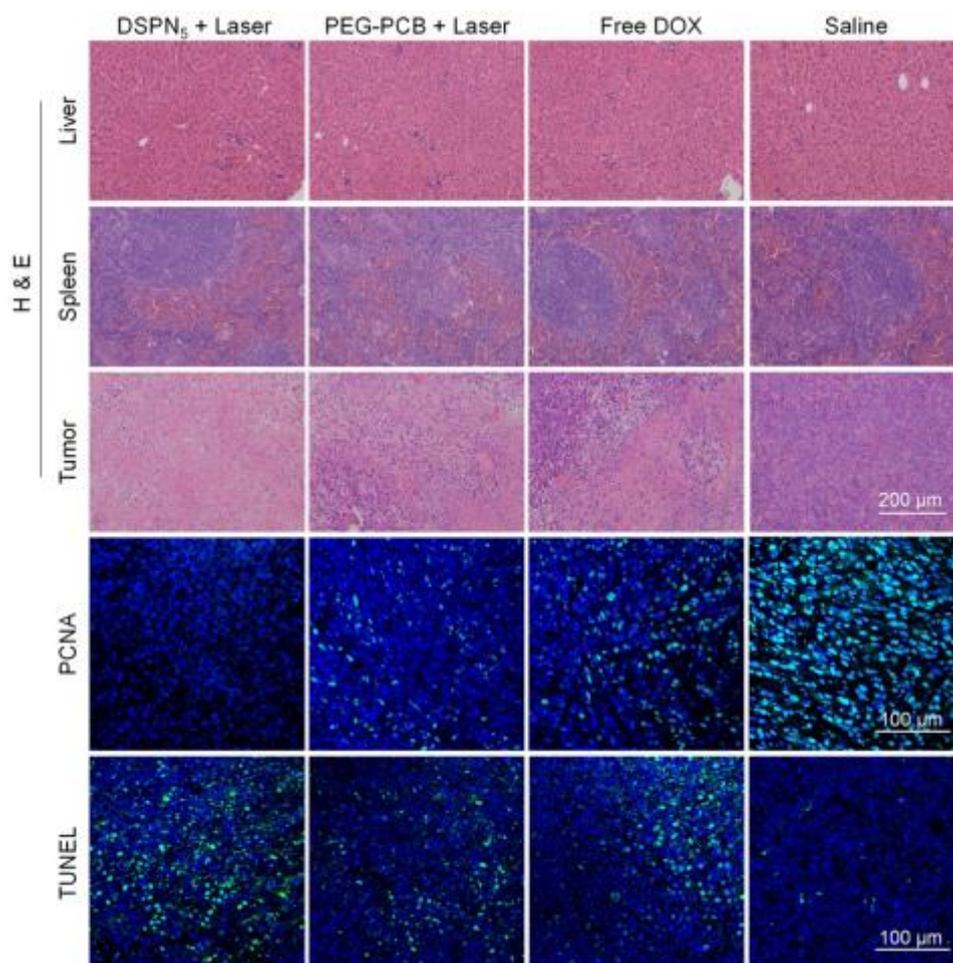

Fig. 6. Histological analysis. (a) H & E staining of livers, spleens and tumors for 4T1 tumor-bearing mice at day 16 after photothermal treatment with saline, free DOX, PEG-PCB, or DSPN$_5$. (b) Fluorescence PCNA and (c) TUNEL staining of tumors on 4T1 tumor-bearing mice at 16 d after photothermal treatment with saline, free DOX, PEG-PCB, or DSPN$_5$. Green fluorescence indicated signals of PCNA and TUNEL staining while blue fluorescence indicated nucleus staining.

To further validate the enhanced therapeutic effect of DSPN$_5$, all the mice were sacrificed at day 16 and histological analysis was performed on tumors and different organs by hematoxylin and eosin (H & E) staining, fluorescent proliferating cell nuclear antigen (PCNA) and TdT-mediated dUTP-biotin nick end labeling (TUNEL) staining. No noticeable histopathological damage was found in the liver or spleen of mice treated with free DOX, PEG-PCB, and DSPN$_5$

14

after PTT, while typical nuclear dissociation was clearly observed in tumor tissues of the same groups, with the overall severest dissociation found in DSPN$_5$ injected mice after PTT treatment (Fig. 6a). Besides, PCNA staining of tumor regions on mice demonstrated that the reproduction capacity of cancer cells was reduced in free DOX, PEG-PCB, or DSPN$_5$ treated mice after PTT (Fig. 6b), which was not observed saline treated mice without laser irradiation. In comparison with the sparse green fluorescent dots observed in free DOX or PEG-PCB treated mice, no fluorescent dots could be found in DSPN$_5$ treated group, which implied the minimum proliferation capability of cancer cells caused by chemo-photothermal therapy. Similarly, TUNEL staining of tumor region of mice showed the evident apoptosis of cancer cells observed in free DOX, PEG-PCB, or DSPN$_5$ treated mice after PTT (Fig. 6c). As indicated by the stronger green fluorescence in the tumor tissue, DSPN$_5$ caused severer apoptosis than PEG-PCB and free DOX. The outcome of histological analysis validated at cellular level the superiority of DSPN$_5$ over PEG-PCB and free DOX for antitumor effect, which was consistent with the result of *in vivo* antitumor experiments (Fig. 5c).

3. Conclusion

We have demonstrated a simplified theranostic nanoagent DSPN$_5$ for NIR fluorescence/PA imaging guided chemo-photothermal therapy. Such a concise design was based on an amphiphilic polymer PEG-PCB synthesized by PEGylation of semiconducting polymer via click chemistry. By virtue of the hydrophobic π-conjugated backbone, PEG-PCB not only acted as the contrast agent for both NIR fluorescence and PA imaging, but also served as the therapeutic agent for PTT as well as the drug delivery system for chemotherapy. Taking advantage of such trifunctionality, PEG-PCB was utilized to encapsulate DOX to obtain the greatly simplified nanotheranostic system (DSPN$_5$) with only dual components but multimodal theranostic capabilities. Due to the small size of nanoparticle, DSPN$_5$ was able to passively accumulate in the tumor site of living mice via EPR effect, allowing for effective NIR

fluorescence and PA imaging of tumor. After systemic administration of DSPN5, the PA amplitude of tumor region on DSPN5-treated mice could be 3.8-fold higher than that of the tumor background before systemic administration. Moreover, both *in vitro* and *in vivo* characterization of combination therapy revealed the superior antitumor efficacy of DSPN5 over PEG-PCB or free DOX owning to the synergistic effect of chemotherapy and PTT. Superior to PEG-PCB mediated PTT or DSPN5 mediated chemotherapy, DSPN5 mediated chemo-photothermal therapy totally inhibited the tumor growth during experimental period, which was further validated at cellular level by histological analysis.

Our study thus provides a molecular engineering approach to integrate desired properties into one polymer for multimodal nanotheranostics. Because the side chains of amphiphilic SPs can be easily modified with Fluorine-19, further integration of magnetic resonance imaging (MRI) into the system could be feasible. In addition to chemotherapy drugs, other therapeutic agents such as immunoadjuvants can also be encapsulated into such polymer for other therapeutic purpose.

4. Experimental Section

Chemicals: All chemicals were purchased from Sigma-Aldrich unless otherwise mentioned.

Synthesis of PCB-Br: 2,6-dibromo-4,4-bis(6-bromohexyl)-4H-cyclopenta[2,1-b:3,4-b']dithiophene (50 mg, 0.075 mmol), 4,7-bis(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)benzo[c][1,2,5]thiadiazole (28 mg, 0.075 mmol), Pd(PPh3)4 (5.5 mg, 0.052 mmol) and K2CO3 (122.49 mg, 0.75 mmol) were placed in a 50 mL Schlenk tube. Then toluene (2.5 mL) with methyltrioctylammonium chloride (1 mg) and water (1.25 mL) were added to the Schlenk tube subsequently. The mixture was degassed by freeze-pump-thaw circles for three times. The reaction was carried out at 100 ºC under nitrogen atmosphere for 2 h. Then the solvent was removed under reduce pressure. The obtained solid was re-dissolved by excess dichloromethane and washed with water for three times. The organic phase was concentrated

and precipitated into excess methanol. The obtained solid was washed three times by methanol and then dried under vacuum to obtain product. ^{1}H NMR (300 MHz, CDCl$_3$) δ 8.12 (s, 1H), 7.89 (s, 1H), 7.61 (s, 2H), 3.33 (s, 3H), 1.90 (d, $J = 93.0$ Hz, 8H), 1.25 (s, 12H), 0.87 (d, $J = 7.7$ Hz, 4H).

Synthesis of PCB-N$_3$: SP-Br (10 mg) and sodium azide (4 mg) were dissolved in a mixture of THF (12 mL) and DMF (6 mL). The mixture was stirred at 25 ºC overnight. After that the solvent was removed under reduced pressure, an excess of dichloromethane was added to the residue. The resulted solution was washed three times with water and the organic phase was collected to dry over Na$_2$SO$_4$. The dichloromethane was removed and SP-N$_3$ was obtained. 1H NMR (300 MHz, CDCl3) δ 8.11 (s, 1H), 7.89 (d, J = 8.5 Hz, 1H), 7.72 – 7.41 (m, 2H), 3.18 (s, 3H), 2.02 (s, 4H), 1.28 (d, J = 17.3 Hz, 18H), 0.87 (d, J = 6.9 Hz, 3H).

Synthesis of PEG-PCB: SP-N$_3$ (10 mg) was dissolved in THF (12 mL). CuBr (11 mg), PMDETA (66.8 mg) and methoxy-PEG-alkyne (M$_n$ = 2000, 150 mg) were added into previous solution subsequently. The reaction was carried out at room temperature under nitrogen atmosphere for 48 h. After that the solvents were removed under reduced pressure and the remaining residue was dissolved into water. The resulted solution was dialysis against DI water to remove the salt and excess methoxy-PEG-alkyne in the system. The SP-PEG was obtained after lyophilization. ^{1}H NMR (300 MHz, CDCl$_3$) δ 7.71 (s, 1H), 7.61 (s, 1H), 7.53 – 7.42 (m, 2H), 4.00 – 3.39 (m, 320H), 1.76 (d, $J = 53.7$ Hz, 32H), 1.31 (d, $J = 33.2$ Hz, 32H), 0.87 (d, $J = 7.3$ Hz, 24H).

Preparation of PEG-PCB Nanoparticles: PEG-PCB (1 mg) was dissolved in 1 mL THF by bath sonication. The obtained solution (1 mg/mL) was rapidly injected into a mixture of deionized water (9 mL) and THF (1 mL) solution under continuous sonication at a power output of 110 W for 1 min. THF in the solution was then removed by a nitrogen flow. The obtained solution was filtrated through a 0.22 μm PCDF syringe driven filter (Millipore). The PEG-PCB

solution was then concentrated by centrifugation at 2600 rpm for 25 min and subsequently diluted to different concentrations by $1 \times$ PBS (pH = 7.4) for further use.

Preparation of DSPN5: DSPN5 was prepared via nanoprecipitation of DOX and PEG-PCB under controlled pH condition. DOX hydrochloride (DOX·HCl, 2 mg) was first dissolved in dimethyl sulfoxide (DMSO) (0.2 mL). Triethylamine (5 μL) was then added to the DOX·HCl DMSO solution (10 mg/mL) under bath sonication for 10 min. The resulted solution was subsequently mixed with the PEG-PCB solution in THF (1 mL, 1mg/mL). The obtained mixture was dialyzed in $1 \times$ PBS buffer (pH = 7.4) for 48 h to remove excess free DOX. The resulted DSPN5 solution was purified by filtration through a 0.22 μm PCDF syringe driven filter (Millipore) and then concentrated by ultrafiltration. Concentration of DOX encapsulated into nanoparticles was quantified by the absorbance of DSPN5 at 500 nm after subtracting the absorbance of PEG-PCB at this wavelength. DSPN5 was lyophilized followed by reconstitution to evaluate the LC. LC was calculated by the following equation: weight of encapsulated DOX / weight of DSPN5 $\times$ 100%. Weight of encapsulated DOX was measured by UV-vis spectrometer.

Characterization of Nanoparticles: ^{1}H NMR spectra were obtained by Bruker Avance II 300 MHz NMR with CDCl3 as the solvent. DLS was conducted on a Malvern Nano-ZS Particle Sizer. TEM images were acquired by a JEM 1400 transmission electron microscope with the accelerating voltage ranging from 40 to 120 kV. UV-Vis absorption spectra were recorded by Shimadzu UV-2450 spectrometer. Fluorescence spectra were obtained by Fluorolog 3-TCSPC spectrofluorometer (Horiba Jobin Yvon). An 808 nm high power NIR laser (operating mode, CW; output power after fiber, 2.5 W; LED display; diode current, multimode fiber; fiber core diameter, 400 μm; fiber connector, SMA905, with tunable laser driver module of 0-100%) purchased from CNI Co., Ltd. was used for PTT treatments. The laser power output was

measured by power meter. IR thermal images was captured by photothermal camera FLIR T420.

PA Instrumentation: An optical parametric oscillator (OPO) (Continuum, Surelite) pumped by a Q-switched 532 nm Nd: YAG laser was used as the laser source to generate tunable laser pulses within 680-900 nm wavelength range with 100 mJ/pulse energy at 10 Hz repetition rate. Nanoparticle solution was placed inside a low-density polyethylene (LDPE) tube with an inner diameter (i.d.) of 0.59 mm and an outer diameter (o.d.) of 0.78 mm. The LDPE tube containing samples and the ultrasound transducer (UST) (V323-SU/2.25MHz, 13 mm active area, and 70% nominal bandwidth, Panametrics) were both immersed in water to couple PA signals to UST. The LDPE tube was irradiated with laser pulses of wavelengths ranging from 680 to 920 nm with 10 nm increment. PA signals were collected by UST, amplified with a gain of 50 dB, and then band pass filtered (1-10 MHz) by a pulse/receiver unit (Olympus-NDT, 5072PR).

In Vitro PTT of Nanoparticles: 200 μL of PEG-PCB (PCB, 10 μg/mL), $DSPN_5$ (PCB, 10 μg/mL; DOX, 50 μg/mL), free DOX (DOX, 50 μg/mL), and PBS solutions were exposed to 808 nm laser with the power intensity of 1 W/cm^2, respectively. Temperature of solution was recorded every 20 s by an IR thermal camera until it reached the maximum (6 min).

In Vitro Drug Release Property of $DSPN_5$: 1 mL $DSPN_5$ solution (PCB, 0.2 mg/mL; DOX, 1 mg/mL) was filled into dialysis tubing (MW, 3000) which was then sealed and immersed in 5 mL PBS buffer of different pH conditions (pH = 5.5, 6.5, and 7.4), respectively. The dialysis reservoir was incubated in 37 ℃ water bath with constant shaking. At designated time points, the PBS buffer was removed to quantify the amount of released DOX while another 5 mL fresh PBS buffer was added to the dialysis reservoir for further study. The concentration of released DOX was measured by UV-Vis absorption spectroscopy.

Cell Culture and Cell Imaging: 4T1 mammary carcinoma cells were purchased from the American Type Culture Collection (ATCC). 4T1 cells were cultured in Dulbecco's Modified Eagle Medium (DMEM) with 10% fetal bovine serum (FBS) and antibiotics (10 U/mL penicillin and 10 mg/mL streptomycin) in an atmosphere of 5% CO_2 and 95% humidified air at 37 ℃. The cells were seeded in confocal dishes and incubated with PBS, PEG-PCB (PCB, 10 μg/ml), and $DSPN_5$ (PCB, 10 μg/ml; DOX, 50 μg/ml) respectively for 12 h before replacement of medium with fresh DMEM and nuclei staining by DAPI. Confocal images were captured by a LSM710 confocal laser scanning microscope (Carl Zeiss, Germany) with the excitation wavelength of 405 nm for DAPI, 488 nm for DOX and 633 nm for PCB.

In Vitro Chemo-Photothermal Therapy: Cells were seeded in 96-well plates (6000 cells in 200 μL DMEM per well) for 24 h, and then free DOX, PEG-PCB, or $DSPN_5$ (final PCB concentration 2, 5, 7, 10, and 15 μg/mL; final DOX concentration 10, 25, 35, 50, and 75 μg/mL) was added to the culture medium of cells separately. After incubation for 12 h, cells were treated with or without laser irradiation of 1 W/cm^2 for 6 min. After PTT treatment, cells were incubated for another 12 h. Then the medium was removed and fresh DMEM with MTS (0.1 mg/mL, 20 μL/well) was added to cells. After incubation for 4 h, the absorbance of MTS at 490 nm was measured by a SpectraMax M5 microplate/cuvette reader and the cell viability was quantified by the ratio of the absorbance of cells incubated with samples to that of control cells incubated with DMEM only.

Tumor Mouse Model: All animal experiments were performed in compliance with the guidelines established by Tianjin Committee of Use and Care of Laboratory Animals and the overall project protocols were approved by the Animal Ethics Committee of Nankai University. To establish tumors in six-week-old BALB/c mice, two million 4T1 cells suspended in 50 mL of 50 v/v% mixture of Matrigel in supplemented DMEM (10% FBS, 1% pen/strep, 100 U/mL penicillin, and 100 μg/mL streptomycin) were injected subcutaneously in the shoulders of the

mouse. Tumors were grown until a single aspect was ≈ 7 mm (10-15 days) before used for *in vivo* imaging and chemo-photothermal treatments.

In Vivo Fluorescence Imaging: Whole-body fluorescence imaging of mice was conducted by a Cri Maestro whole animal imaging system (Caliper Life Sciences, Hopkinton, MA). BALB/c mice bearing xenograft 4T1 tumors were administered with PEG-PCB (PCB, 30 µg per mouse) (n = 3) or DSPN$_5$ (PCB, 30 µg; DOX, 150 µg per mouse) (n = 3) through tail vein injection. Fluorescence images of mice were acquired at different time points (2, 4, 6, 8, 24 h) post-injection of nanoparticles. Quantification of fluorescence in each image was performed by Nuance software.

In Vivo PA Imaging: PA imaging of tumor region were performed by the Endra Nexus128 PA imaging system to acquire images at 680 nm. 4T1 tumor xenografted BALB/c mice were first anesthetized by 2% isoflurane in oxygen and then placed in the imaging system to determine the endogenous PA signal of tumor region before administration of samples. PEG-PCB (PCB, 30 µg per mouse) (n = 3), DSPN$_5$ (PCB, 30 µg; DOX, 150 µg per mouse) (n = 3), or saline (150 µL) (n = 3) were then systematically administered through tail vein injection. Data were acquired through a continuous model that tool 12 s to obtain one data set. 3D PA images were reconstructed offline using data acquired from all 128 transducers at each view and back-projection algorithm. The algorithm corrects for pulse-to-pulse variations in the laser intensity and small changes in the temperature that affect acoustic velocity in the water.

In Vivo Chemo-Photothermal Therapy: 4T1 tumor xenografted BALB/c mice were systemically administered with PEG-PCB (PCB, 30 µg per mouse) (n = 3), DSPN$_5$ (PCB, 30 µg; DOX, 150 µg per mouse) (n = 3), free DOX (DOX, 150 µg per mouse) (n = 3), or saline (n = 3) via a single tail vein injection. At 6 h post injection, tumor regions of living mice were exposed or without exposure to 808 nm laser of 0.3 W/cm^2. IR thermal camera was used to

21

record the temperature change of the tumor every 15s for 5 min after irradiation. The tumor size was measured by caliper every other day and calculated as follows: volume = (tumor length) $\times$ (tumor width)^2/2. Relative tumor size was calculated as V/V_0 (V_0 was the initial tumor volume). Mice with tumors larger than 1000 mm^3 should be euthanized according to the standard animal protocol.

Biodistribution Method: After 24 h post-injection of PEG-PCB (PCB, 30 μg per mouse) (n = 3) or DSPN$_5$ (PCB, 30 μg; DOX, 150 μg per mouse) (n = 3), the mice were sacrificed by CO_2 asphyxiation and tumor, heart, liver, spleen, lung, kidney, skin, muscle, and bones were harvested for *ex vivo* fluorescence imaging to quantify the biodistribution of nanoparticles.

Histological Studies: After 16 days of PTT, the mice treated with PEG-PCB (PCB, 30 μg per mouse) (n = 3), DSPN$_5$ (PCB, 30 μg; DOX, 150 μg per mouse) (n = 3), or saline (n = 3) were sacrificed. The tumor, liver, and spleen were fixed in 4% formalin. Paraffin embedded sectioning was then performed for H&E staining. The obtained slices were next exa mined under a digital microscope (Leica QWin). As for PCNA staining, sliced formalin-fixed tumor samples were used for confocal immunofluorescent analysis by PC10 Mouse mAb (#2586, Cell Signaling Technology). Fixed tumor sections were treated following the protocol of In Situ Cell Death Detection Kit (Roche Applied Science) for TUNEL apoptosis staining and Hoechst 33342 was used for nuclear counterstaining.

Data Analysis: *In vivo* PA signal intensities were measured by region-of-interest (ROI) anal ysis using OsiriX. Fluorescence signal intensities were measured by ROI analysis using ImageJ. Results were expressed as the mean $\pm$ SD deviation unless otherwise stated. All statistical calculations were performed using GraphPad Prism v.5 (GraphPad Software, Inc., CA, USA).
