A micromechanics method is developed to investigate the effects of porosity in the matrix and the polarization orientations of the piezopolymer matrix and the piezoceramic fibers on the performance of 1–3 piezoelectric composites. The Mori–Tanaka (MT) method is first used to homogenize the porous piezopolymer matrix, and then the MT method for piezoelectric composites is used to analyze the porous piezopolymer matrix with embedded piezoceramic fibers. Results show that the performance of the composites is significantly enhanced by the presence of pores in the matrix and further enhanced by the opposite polarization orientation of the matrix and the fibers. © 2013 AIP Publishing LLC. [http://dx.doi.org/10.1063/1.4822109]

Piezoelectric composites or piezocomposites with 1–3 connectivity are an important class of materials for biomedical imaging and underwater acoustic applications.¹ These piezocomposites are flexible to conform to curved surfaces and have lower acoustic impedance and higher electromechanical coupling in comparison with single phase piezoceramic materials.

Analytical models²–¹⁰ and finite element models¹¹–¹⁴ have been presented to study 1–3 piezocomposites with a non-porous matrix. Simple models for composites used in ultrasonic transducer application have been presented by Smith and co-workers²–⁴ and Chan and Unsworth.⁵ Nan and Weng⁶ presented a model using the effective medium theory for composites with piezopolymer matrix and piezoceramic fibers that was used to investigate the influence of polarization orientation of the piezoelectric matrix and fibers on the performance of the composites. Kar-Gupta and Venkatesh⁷ presented an equivalent layer composite model for composites where both the matrix and the fibers are anisotropic and piezoelectric active. Dunn and Taya⁸,⁹ and Odegard¹⁰ developed analytical models using the self-consistent, Mori–Tanaka (MT), and differential micromechanics theories to predict the effective electromechanical properties of piezocomposites.

Further studies have shown that the additional porosity in the matrix,¹⁵–¹⁹ modification of the poling orientations of the piezoelectric matrix and fibers,⁶,¹²,¹⁰ and the use of a flexible piezoelectric matrix²⁰ can enhance the performance of the 1–3 piezocomposites. Thus, motivated by these findings, the objectives of the present study are: (1) to develop a micromechanics-based method to analyze the performance of 1–3 piezocomposites with a porous piezopolymer matrix; and (2) to conduct a parametric study to examine the effects of the porosity in the piezopolymer matrix and the polarization orientations of the piezopolymer matrix and the piezoceramic fibers on the performance of 1–3 piezocomposites.

The micromechanics-based method for 1–3 piezocomposites presented here is a two-step process. First, the porous piezopolymer matrix is homogenized using MT model. Then, the porous matrix, which is assumed to be transversely isotropic, is embedded with piezoceramic fibers and analyzed using MT approach.⁸,⁹,¹⁶ The method is then used to study 1–3 piezocomposites for underwater acoustic transducer (hydrophone) and biomedical imaging applications, which consists of an array of parallel piezoceramic fibers embedded in a piezopolymer matrix, as shown in Fig. 1.

For linear piezoelectric materials, the constitutive equations are¹⁶,²²

\[
\Sigma_{ij} = E_{ijMn}Z_{Mn},
\]

where \(\Sigma_{ij}, E_{ijMn}, \) and \(Z_{Mn}\) are

\[
\Sigma_{ij} = \begin{cases} 
\sigma_{ij} & J = 1, 2, 3 \\
D_i & J = 4,
\end{cases}
\]

\[
E_{ijMn} = \begin{cases} 
C_{ijmn} & J, M = 1, 2, 3 \\
\epsilon_{ij} & J = 1, 2, 3; M = 4 \\
\epsilon_{mn} & J = 4; M = 1, 2, 3 \\
-K_{Mn} & J, M = 4,
\end{cases}
\]

\[
Z_{Mn} = \begin{cases} 
\epsilon_{mn} & M = 1, 2, 3 \\
-E_n & M = 4,
\end{cases}
\]

where \(\sigma_{ij}, \epsilon_{ij}, E_i, \) and \(D_i\) are the stress tensor, strain tensor, electric field vector, and electric displacement vector, respectively. \(C_{ijmn}, \epsilon_{ij}, \) and \(K_{Mn}\) are the elastic stiffness tensor, piezoelectric tensor, and permittivity tensor, respectively.

Equation (1) can be expressed in matrix form as

\[
\Sigma = EZ,
\]

where

\[
\Sigma' = \begin{bmatrix} 
\sigma_{11} & \sigma_{22} & \sigma_{33} & \sigma_{31} & \sigma_{12} & D_1 & D_2 & D_3
\end{bmatrix},
\]

\[
Z' = \begin{bmatrix} 
\epsilon_{11} & \epsilon_{22} & \epsilon_{33} & \gamma_{23} & \gamma_{13} & \gamma_{12} & E_1 & E_2 & E_3
\end{bmatrix},
\]

Given by the matrix, the effective elastic moduli using the MT method are 

$$E = E' + v_x (E' - E_m) A_m' [(1 - v_x) I + v_x (A_m')^{-1}],$$  

where $E'$ is the effective electroelastic moduli of the composite, $E_m'$ is the electroelastic moduli of the porous matrix, $E_m$ is the electroelastic moduli of the piezoelectric fiber, $v_x$ is the volume fraction of the piezoelectric fiber, $A_m$ is the dilute concentration tensor and where the mechanical properties of the reference material (porous piezopolymer matrix) are those determined using Eq. (1). The dilute mechanical concentration tensor $A_m'$ is

$$A_m' = [I + S' (E' - E_m)^{-1}]^{-1},$$

where $S'$ is the piezoelectric Eshelby tensor.9,24

The hydrostatic parameters that are used to measure the performance of underwater acoustic transducers or hydrophones are: (a) hydrostatic charge coefficient $g_{hh}$; (b) hydrostatic voltage coefficient $g_{hh}$; and (c) hydrophone figure of merit (FOM) $d_{hh}g_{hh}$. These parameters can be determined by using the calculated effective electroelastic properties using Eq. (11), and the higher the value of each of these parameters, the higher is the sensitivity of the transducer.17

The hydrostatic charge coefficient $d_{hh}$ is defined by 

$$d_{hh} = d_{33} + d_{32} + d_{33}. Large values of d_{hh} are desirable for hydrophones in order to achieve enhanced sensitivity to the detection of sound waves. The corresponding hydrostatic voltage coefficient $g_{hh}$ is defined by $g_{hh} = d_{hh}^2/k_{33}. A useful FOM is the product of $d_{hh}$ and $g_{hh}$, which should be maximized in order to enhance the signal-to-noise ratio of the transducer.21

For biomedical imaging applications, the electromechanical coupling $k_t$ and the acoustic impedance $Z$ are used to measure the performance of medical ultrasonic imaging transducers, where a low acoustic impedance and high electromechanical coupling is desired.4 The electromechanical coupling $k_t$ is defined as 

$$k_t = \sqrt{1 - C_{33}/C_{33}},$$

where $C_{33}$ is the compliance and $C_{33}$ is the acoustic impedance. The results for 1–3 piezocomposites with cylindrical pores oriented along the $x_3$-axis consists of PZT7A fibers and P(VDF–TrFE) matrix,16,20 as shown in Fig. 1. The fibers are aligned and poled along the $x_3$-direction. The results for 1–3 piezocomposites with a non-piezoelectric Araldite D matrix16 are also presented for purpose of comparison. When the non-piezoelectric matrix is dense (non-porous) the results are identical to the results using the micromechanics model by Dunn and Taya.9

Figures 2(a)–2(c) show the effective hydrostatic parameters $d_{hh}$, $g_{hh}$, and $d_{hh}g_{hh}$ with respect to the piezoelectric fiber.
volume fraction \( v_f \) of the 1–3 PZT/P(VDF–TrFE) piezocomposites with cylindrical pores. The results for piezocomposites with parallel (0°) and antiparallel (180°) orientations of the piezopolymer matrix with respect to the piezoceramic fiber and with 0%, 10%, 20%, and 30% volume of porosity in the matrix are presented. It can be seen that the peak values of \( d_{33}, g_h, \) and \( d_{33}g_h \) are much greater for the piezocomposites with piezoelectric polymer P(VDF–TrFE) matrix than for the piezocomposites with non-piezoelectric polymer Araldite D matrix. Furthermore, these parameters increase as the volume fraction of the porosity increase for up to \( v_f < 0.3 \). The polarization orientation has a more pronounced effect on the effective parameters of the piezocomposites for up to \( v_f < 0.3 \). The peak values of the effective parameters \( d_{33}, g_h, \) and \( d_{33}g_h \) being higher for the antiparallel orientation (180°) and attained at lower volume fraction of the piezoceramic fibers as compared with the results for the parallel orientation (0°).

The electromechanical coupling \( k_t \) of the composites with respect to the fiber volume fraction \( v_f \) is shown in Fig. 3(a). It is observed that \( k_t \) increases as the volume fraction of the porosity increases, with \( k_t \) being higher for the antiparallel orientation. The effective electromechanical coupling \( k_t \) vs the effective acoustic impedance \( Z \) for the piezoelectric composites is shown in Fig. 3(b). It can be seen that \( k_t \) first increases rapidly with \( Z \) and approaches an asymptotic value after \( Z = 6 \) and that \( k_t \) further increases as the volume of porosity increases. The composites with antiparallel orientation reach higher \( k_t \) values at lower \( Z \), as compared with the composites with parallel orientation.

In summary, the presence of porosity enhanced the effective hydrostatic performance parameters of the 1–3 piezocomposites by increasing the peak values of these parameters, since the peak values increased as the volume of porosity increased. The peak values were observed to be higher and attained at lower fiber volume ratio for composites with piezopolymer matrix and piezoceramic fibers poled in the opposite directions than composites with matrix and fibers poled in the same direction. The porosity in the piezopolymer matrix also improved the performance of the 1–3 piezocomposites by increasing the electromechanical coupling while reducing the acoustic impedance of the composite. The electromechanical coupling increased as the volume of the porosity in the matrix is increased and higher
electromechanical coupling of the composites are attained when the piezopolymer matrix and piezoceramic fibers are poled in the opposite directions.

We thank the anonymous reviewer for the valuable contributions.

24Note that Eq. (9) enables us to evaluate the electroelastic moduli of the porous piezoelectric matrix, and then these constants are used at averaging to obtain the effective electromechanical properties of the piezoelectric composite as a whole. In this case, the size (diameter) of the pores is much less than the piezoceramic fibers. These fibers are embedded into the homogeneous medium and do not “feel” a single pore.
