Relation between bare lattice coupling and $\overline{MS}$ coupling at one loop with general lattice fermions

David H. Adams*

Department of Physics and Astronomy, Seoul National University, Seoul, 151-747, South Korea* and Physics Department, National Taiwan University, Taipei 106, Taiwan R.O.C. and Physics Department, Florida International University, 11200 SW 8th Street, Miami, Florida 33199, USA

(Received 9 May 2008; published 25 July 2008)

A compact general integral formula is derived from which the fermionic contribution to the one-loop coefficient in the perturbative expansion of the $\overline{MS}$ coupling in powers of the bare lattice coupling can be extracted. It is seen to reproduce the known results for unimproved naive, staggered and Wilson fermions, and has advantageous features which facilitate the evaluation in the case of improved lattice fermion formulations. This is illustrated in the case of Wilson clover fermions, and an expression in terms of known lattice integrals is obtained in this case which gives the coefficient to much greater numerical accuracy than in the previous literature.

I. INTRODUCTION

When transforming results from lattice simulations into a continuum scheme such as $\overline{MS}$ it is often desirable to know the perturbative expansion of the renormalized coupling in powers of the bare lattice coupling. This is useful as an intermediate step for relating the $\overline{MS}$ coupling to the coupling defined in nonperturbative lattice schemes such as the ones based on the static quark potential [1,2] and Schrödinger functional [3,4], and is also needed to translate bare lattice quark masses into the $\overline{MS}$ scheme (see, e.g., [5,6]). The one-loop coefficient in the expansion is of further interest because it determines the ratio of the lattice and $\overline{MS}$ Λ parameters [7–14]. Moreover, the one-loop coefficient is also needed for determining the two-loop relation between the couplings, from which the third term in the lattice beta function (governing the approach to the continuum limit) can be determined [3,15–19].

In this paper we derive, for general lattice fermion formulation, a compact general integral formula from which the fermionic contribution to the one-loop coefficient in the perturbative expansion of the $\overline{MS}$ coupling in powers of the bare lattice coupling can be extracted. The motivations for pursuing this are as follows. First, given the plethora of lattice fermion actions currently in use, and the likelihood of new ones or improved versions of present ones being developed in the future, it is desirable where possible to have general formulas from which quantities of interest can be calculated without having to do the calculation from scratch each time. Second, it is desirable to have independent ways to check the computer programs used these days to perform lattice perturbation theory calculations via symbolic manipulations. Third, by reducing the calculation to a manageable number of one-loop lattice integrals one can more easily achieve greater numerical precision than with symbolic computer programs. This is important, since, as emphasized in [20], the one-loop results need to be determined with very high precision to achieve reasonable precision in the two-loop result. As a demonstration that the general formulas of this paper are useful in this regard, we apply them to obtain the fermionic contribution to the one-loop coefficient in the case of Wilson clover fermions [21] to almost twice as many significant decimal places as in the previous literature.

As reviewed in Sec. II, determining the fermionic contribution to the one-loop coefficient reduces to determining a constant $c_f$ arising in a logarithmically divergent one fermion loop lattice Feynman integral $I(am)$, which has the general structure

$$I(am) = \frac{1}{24\pi^2} \log(a^2m^2) + c_f.$$  

Here $a$ is the lattice spacing and $m$ an infrared regulator fermion mass. The numerical factor in the log term is universal, whereas $c_f$ depends on the details of the lattice fermion formulation. $I(am)$ arises from the one fermion loop contribution to the gluonic two-point function, and it is from this that it was evaluated in previous works for specific lattice fermion formulations. However, Ward identities allow $I(am)$ to also be evaluated from the gluonic three- or four-point functions. In this paper we evaluate $I(am)$ from the one fermion loop contribution to the gluonic four-point function. In this case there are five lattice Feynman diagrams to consider rather than the two diagrams for the gluonic two-point function (see Fig. 1). Nevertheless, evaluation of $I(am)$ from the four-point function turns out to be advantageous. The diagrams are evaluated at vanishing external momenta without the need to first take momentum derivatives, and we find three nice properties:

(i) Only one of the five diagrams is logarithmically divergent—it is the first $n=4$ diagram in Fig. 1. The other four diagrams are all convergent.

*dadams@phya.snu.ac.kr

*Current address.
The logarithmically divergent diagram is not affected by changes in how the link variables are coupled to the fermions (e.g., it is unchanged by adding staples, clover term, etc.). Consequently, it is the same for improved and unimproved versions of the lattice fermion formulation (provided the free field formulations are the same).

The four convergent diagrams, or subsets of them, vanish when the lattice Dirac operator is sufficiently simple. In particular, they all vanish for unimproved Wilson and staggered fermions, also when the Naik term [22] is included.

Thus for improved versions of Wilson and staggered fermions the only new quantities to compute relative to the unimproved case are the four convergent one-loop lattice integrals.\(^1\)

The main result in this paper is a general integral formula for \(I(\alpha m)\) obtained by evaluating the contributions from the five \(n = 4\) Feynman diagrams in Fig. 1 for general lattice fermion formulation, from which the desired constant \(c_I\) can be extracted. Specifically, we do the following:

(a) evaluate the contribution from the logarithmically divergent diagram, deriving a quite explicit general formula which is seen to reproduce previous results for the cases of unimproved Wilson and naive/staggered fermions, and

(b) derive formulas for, and describe a straightforward procedure for evaluating, the contributions from the four convergent diagrams. We illustrate this in the case of Wilson clover fermions. The general formulas lead to integrals to which the method of Ref. [23] can be applied, reducing the integrals to basic lattice integrals that are already known to high precision. The application of our result to other lattice fermion formulations such as Asqtad staggered fermions [24] and overlap fermions [25] will be made in future work.

The paper is organized as follows. Section II reviews the one-loop expansion of the \(\overline{MS}\) coupling in the bare lattice coupling, using the background field approach. In Sec. III we derive an initial expression for \(I(\alpha m)\) as the sum of contributions from the five \(n = 4\) diagrams in Fig. 1 and point out the properties (i), (ii), and (iii) mentioned above. Rather than evaluating the diagrams directly, we infer them from perturbative expansion of the fermion determinant, which is easier. From this the general formulas and applications mentioned in (a) and (b) above are derived in Secs. IV and V, respectively. The concluding Sec. VI describes applications to be carried out in future work, as well as the possibility of deriving similar results for the gauge-ghost contribution to the one-loop coefficient. Also, it is pointed out that the present results are relevant for a previous proposal for constructing the gauge field action on the lattice from the lattice fermion determinant [26]. Specifically, our results give an expression for the coefficient of the Yang-Mills action that arises in that proposal. Some technical details of our calculations are provided in two appendices.

**II. GENERALITIES OF THE ONE-LOOP RELATION BETWEEN BARE LATTICE COUPLING AND \(\overline{MS}\) COUPLING**

The gauge field quantum effective action \(\Gamma(A)\) in Euclidean spacetime can be expressed (prior to gauge fixing) as

\[
e^{-\Gamma(A)} = \int \mathcal{D}Q \mathcal{D}\bar{\psi} \mathcal{D}\psi e^{-(1/g^2)S_{\text{YM}}(A+gQ)-\int \mathcal{D}\phi (A+gQ)\phi} \tag{2}
\]
where $S_{YM}$ is the Yang-Mills (YM) action and $D(A + gQ)$ is the Dirac operator coupled to $A + gQ$ where $A$ is the background gauge field and $Q$ the quantum fluctuation field. The gauge group is taken to be SU(N) with the background gauge field and fermion loop. Consequently, for given by a sum of three terms: gauge field loop, ghost loop, and fermion loop. The one-loop contribution to the two-point function is given by a sum of three terms: gauge field loop, ghost loop, and fermion loop. Consequently, for $N_f$ flavors of massless fermions, $\nu_1(p)^{\text{lat}}$ and $\nu_1(p)^{\text{latt}}$ have the general forms

$$\nu_1(p)^{\text{lat}} = -\beta_0 \log(p^2/\mu^2) + c_f^{\text{lat}} + N_f c_f^{\text{latt}}$$

$$\nu_1(p)^{\text{latt}} = -\beta_0 \log(a^2 p^2) + c_f^{\text{latt}} + N_f c_f^{\text{latt}}$$

where $\mu$ is the mass scale in the $\overline{MS}$ scheme, $a$ is the lattice spacing, and

$$\beta_0 = \frac{1}{16\pi^2} \left( N_f \frac{11}{3} - N_f \frac{2}{3} \right).$$

Therefore, to determine $l'_0$ we need to determine the lattice constant $c_f^{\text{lat}}$ for general lattice fermion formulation.

To study $c_f^{\text{lat}}$ it suffices to consider the $N_f = 1$ case which we restrict to henceforth. We proceed by expanding the lattice two-point function $\Gamma^{(2)}(p)_{\mu \nu}$ in powers of the components of $\mathbf{p}$ to second order in $p$ results in an expression of the general form

$$\left[ \Gamma^{(2)}(p)_{\mu \nu} \right]_{1, \text{latt}} = \delta^{ab} \left( p^2 \delta_{\mu \nu} - p_{\mu} p_{\nu} \right) I(a m) + R(p^2/m^2).$$

The constant $c_f^{\text{lat}}$ arises from the gauge and ghost loop contributions; it depends on $N$ and the gauge fixing parameter, while $c_f^{\text{latt}}$ arises from the fermion loop contribution. In the lattice case $c_f^{\text{lat}}$ and $c_f^{\text{latt}}$ also depend on whatever parameters are present in the lattice gauge and fermion actions (e.g., for lattice Wilson fermions $c_f^{\text{lat}}$ depends on the Wilson parameter).

From (7)–(9) we get

$$\frac{1}{g^2} = \frac{1}{g_0^2} + \beta_0 \log(a^2 \mu^2) + l_0$$

where

$$l_0 = l_0^g + N_f l_0^f$$

$$l_0^g = c_f^{\text{MS}} - c_f^{\text{latt}}, \quad l_0^f = c_f^{\text{MS}} - c_f^{\text{latt}}.$$

(Our notations $l_0^g$, $l_0^f$, $l_0^f$ follow the papers of Panagopoulos and collaborators, e.g., [14]). The relation between $g$ and $g_0$ up to one loop now follows from (11)

$$g^2 = g_0^2 \left( 1 - g_0^2 \beta_0 \log(a^2 \mu^2) + l_0 \right) + O(g_0^4).$$

Also, from (11) or (14) the relation between the lattice and $\overline{MS}$ $\Lambda$ parameters is obtained [7–11]

$$\frac{\Lambda_{\text{lat}}}{\Lambda_{\overline{MS}}} = e^{l_0/2\beta_0}.$$

The focus of our attention in this paper is the fermionic contribution to $l_0$, i.e., $l_0^f$ in (13) for general lattice fermion formulation. The continuum constant $c_f^{\text{MS}}$ is well-known (see, e.g., [16])

$$c_f^{\text{MS}} = -\frac{5}{72\pi^2}.$$

In the lattice theory there is only hypercubic rotation symmetry. However, this suffices to obtain (5) in the lattice setting up to terms which vanish for $a \to 0$. Here $I(\alpha)$ is a logarithmically divergent one-loop lattice

PHYSICAL REVIEW D 78, 014512 (2008)

Therefore, to determine $l'_0$ we need to determine the lattice constant $c_f^{\text{lat}}$ for general lattice fermion formulation.

To study $c_f^{\text{lat}}$ it suffices to consider the $N_f = 1$ case which we restrict to henceforth. We proceed by expanding the lattice two-point function $\Gamma^{(2)}(p)_{\mu \nu}$ in powers of the components of $\mathbf{p}$ to second order in $p$ results in an expression of the general form

$$\left[ \Gamma^{(2)}(p)_{\mu \nu} \right]_{1, \text{lat}} = \delta^{ab} \left( p^2 \delta_{\mu \nu} - p_{\mu} p_{\nu} \right) I(a m) + R(p^2/m^2).$$

up to terms which vanish for lattice spacing $a \to 0$. Here $I(\alpha)$ is a logarithmically divergent one-loop lattice
Feynman integral given by

\[ I(\text{am}) = -\frac{\partial}{\partial p} \partial_v [\Gamma^{(2)}_{\text{lat}}(p)]^{11}_{\mu \nu},f,1-\text{loop} |_{p=0} \]

(\(\mu \neq \nu\) no sum) \hfill (18)

\((\partial = \frac{\partial}{\partial p \partial_x})\). By the structural result of [27] it has the general form\(^3\)

\[ I(\text{am}) = \frac{1}{24\pi^2} \log(a^2m^2) + c_I \]  \hfill (19)

where the constant \(c_I\) depends on the details of the lattice fermion formulation. \(R(p^2/m^2)\) in (17) denotes the continuum limit of the remainder term after expanding \([\Gamma^{(2)}_{\text{lat}}(p)]^{ab}_{\mu \nu},f,1-\text{loop}\) to second order in \(p\). It is convergent by power counting and therefore coincides [28] with the corresponding (known) continuum term

\[ R(p^2/m^2) = \frac{1}{4\pi^2} \int_0^1 dx x(1-x) \log \left( \frac{x(1-x)^2 + 1}{m^2} \right) \]  
\[ = \frac{1}{24\pi^2} \log(p^2/m^2) + \frac{1}{4\pi^2} \int_0^1 dx x(1-x) \]  
\[ \times \log \left( \frac{x(1-x)^2 + m^2}{p^2} \right) \]
\[ = \frac{1}{24\pi^2} \log(p^2/m^2) + \tilde{R}(m^2/p^2). \]  \hfill (20)

Substituting (19) and (20) in (17) gives

\[ [\Gamma^{(2)}_{\text{lat}}(p)]^{ab}_{\mu \nu},f,1-\text{loop} = \delta^{ab} (p^2 \delta_{\mu \nu} - p_{\mu} p_{\nu}) \left( \frac{1}{24\pi^2} \right) \]  
\[ \times \log(a^2p^2) + c_I + \tilde{R}(m^2/p^2). \]  \hfill (21)

Comparing this to the expression (5) for \(\Gamma^{(2)}_{\text{lat}}(p)\) with \(v_1(p)\) given by (9), we see that

\[ c_I^{\text{lat}} = c_I + \tilde{R}(0). \]  \hfill (22)

In fact \(\tilde{R}(0)\) is precisely the \(\overline{MS}\) constant \(c_I^{\overline{MS}}\); explicit evaluation of the integral in (20) at \(m = 0\) gives \(\tilde{R}(0) = -5/72\pi^2\). It follows from (13) that

\[ l_0^{I_f} = -c_I. \]  \hfill (23)

Thus the issue is to determine the constant \(c_I\) appearing in the logarithmically divergent one-loop lattice integral \(I(\text{am})\) in (18) and (19). In this paper we are going to derive a compact general formula for \(I(\text{am})\) for general lattice fermions which can then be used to determine \(c_I\).

---

\(^3\)The factor \(1/24\pi^2\) in the log term is fixed by universality [27]; it is minus the fermionic term in \(\beta_0\) with \(N_f = 1\).
where $D_0$ is the free field operator and $D_{\text{int}}$ the interaction part, we start from $D = D_0(1 + D_0^{-1} D_{\text{int}})$ to obtain the expansion

$$\log \det D - \log \det D_0 = \text{Tr} \log (1 + D_0^{-1} D_{\text{int}})$$

$$= \sum_{l=1}^{\infty} \frac{(-1)^{l-1}}{l} \text{Tr} [(D_0^{-1} D_{\text{int}})^l] \quad (32)$$

From this, using $D_{\text{int}} = \sum_{n \geq 1} D_n$ with $D_n$ given by (27), an expansion in powers of $A$ is obtained. It has the general form

$$\log \det D - \log \det D_0 = \sum_{n \geq 1} \int_{p_1, \ldots, p_{n-1}} \Gamma_{\text{det}}^{(n)}(p_1, \ldots, p_{n-1}) \mu_1 \cdots \mu_n \times \text{tr} \hat{A}_{\mu_1}(p_1) \cdots \hat{A}_{\mu_n}(p_n) \quad (33)$$

($p_n = -(p_1 + \ldots + p_{n-1})$). The “$n$-point function” $\Gamma_{\text{det}}^{(n)}(p_1, \ldots, p_{n-1})$ is Taylor expanded in powers of $A$. Gauge invariance and mass-dimension considerations imply that the terms in the expansion can be combined to take the form

$$\log \det D - \log \det D_0 = -I(\text{am}) S_{\text{YM}}(A) + \sum_{r \geq 1} \frac{1}{m^r} S_r(A) \quad (34)$$

up to terms which vanish for $a \to 0$, where each $S_r(A)$ is a gauge invariant function with mass dimension $r \geq 1$. The fact that the coefficient of $S_{\text{YM}}(A)$ is $-I(\text{am})$ is inferred from (17) and (30).

It is clear from (30) and (34) that $I(\text{am})$ can be evaluated from either the two-, three- or four-point function in (33). For the four-point function the relation is

$$I(\text{am}) = -\Gamma_{\text{det}}^{(4)}(0, 0, 0)_{\mu \nu \mu \nu} \quad \mu \neq \nu, \text{ no sum} \quad (35)$$

for any choice of $\mu$ and $\nu$ with $\mu \neq \nu$. Usually $I(\text{am})$ is evaluated from the two-point function via (18), but we will see in the following that it is advantageous to use (35) instead. To evaluate it we start by collecting the terms containing four powers of $A$ in the expansion of $\log \det D$ in (32). These are

$$\begin{align*}
\frac{(-1)^3}{4} & \text{Tr}[(D_0^{-1} D_1)^4] + \frac{(-1)^2}{3} \text{Tr}[(D_0^{-1} D_1)^2 D_0^{-1} D_2] \\
& + \frac{(-1)^1}{2} (2 \text{Tr}(D_0^{-1} D_1 D_0^{-1} D_3) + \text{Tr}[(D_0^{-1} D_2)^2]) \\
& + \frac{(-1)^0}{1} \text{Tr}(D_0^{-1} D_4).
\end{align*} \quad (36)$$

Inserting the expression (27) for each $D_n$, and evaluating the traces in momentum basis, the $\Gamma_{\text{det}}^{(4)}(p_1, p_2, p_3)_{\mu_1 \mu_2 \mu_3 \mu_4}$ in (32) is readily worked out. The resulting expression for $I(\text{am})$ from (35) is as follows. From the functions $d_n$ in (27) we define

$$d_n(k)_{\mu_1 \cdots \mu_n} = d_n(k[0,\ldots,0])_{\mu_1 \cdots \mu_n}, \quad (37)$$

Then

$$I(\text{am}) = I_{(1,1,1,1) \text{am}} + I_{(1,1,2) \text{am}} + I_{(2,2) \text{am}} + I_{(1,3) \text{am}} + I_{(0,4) \text{am}} \quad (38)$$

where

$$I_{(1,1,1,1) \text{am}} = \frac{1}{4} \int_{-\pi}^{\pi} \frac{d^4 k}{(2 \pi)^4} \text{tr} d_0(k)^{-1} d_1(k)_{\mu} \times d_0(k)^{-1} d_1(k)_{\nu} d_0(k)^{-1} d_1(k)_{\mu \nu} \quad (39)$$

$$I_{(1,1,2) \text{am}} = -\int_{-\pi}^{\pi} \frac{d^4 k}{(2 \pi)^4} \text{tr} d_0(k)^{-1} d_1(k)_{\mu} d_0(k)^{-1} d_2(k)_{\mu \nu} \quad (40)$$

$$I_{(2,2) \text{am}} = \frac{1}{2} \int_{-\pi}^{\pi} \frac{d^4 k}{(2 \pi)^4} \text{tr} d_0(k)^{-1} d_2(k)_{\mu \nu} d_0(k)^{-1} d_2(k)_{\mu \nu} \quad (41)$$

$$I_{(1,3) \text{am}} = \int_{-\pi}^{\pi} \frac{d^4 k}{(2 \pi)^4} \text{tr} d_0(k)^{-1} d_1(k)_{\mu} d_0(k)^{-1} d_3(k)_{\nu \mu \nu} \quad (42)$$

$$I_{(0,4) \text{am}} = -\int_{-\pi}^{\pi} \frac{d^4 k}{(2 \pi)^4} \text{tr} d_0(k)^{-1} d_4(k)_{\nu \mu \nu} \quad (43)$$

for any choice of $\mu$ and $\nu$ with $\mu \neq \nu$ (no sum over repeated indices). The traces are over spinor indices alone. Each integral corresponds to an $n = 4$ Feynman diagram in Fig. 1 in Sec. I and the notation reflects the structure of the corresponding diagram. The above integrals could have been derived directly from the Feynman diagrams, with fermion propagator and vertices read off from (27), but it is easier (and equivalent) to use the fermion determinant expansion as we have done above.

The expression of $I(\text{am})$ as the sum of the integrals (39)–(43) is our initial general formula. It has a number of advantageous features which we note in the following.
In light of (28) it is clear that the integral $I_{(1,1,1)}(am)$ diverges logarithmically for $am \to 0$ while the other integrals (40)–(43) are all finite in this limit. The divergent integral necessarily [27] has the general form

$$I_{(1,1,1)}(am) = \frac{1}{24\pi} \log(a^2m^2) + \tilde{c}_I$$  \hspace{1cm} (44)

up to terms which vanish for $a \to 0$. Then $c_I$ is given by

$$c_I = \tilde{c}_I + I_{(1,1,2)}(0) + I_{(2,2)}(0) + I_{(1,3)}(0) + I_{(0,4)}(0).$$  \hspace{1cm} (45)

Next we point out that $I_{(1,1,1)}(am)$, and hence $\tilde{c}_I$, depend only on the free field lattice Dirac operator. This is because $d_I(k)_\mu$ in (39) is determined by $d_0(k)$: for any lattice fermion formulation we have

$$d_I(k)_\mu = \frac{i}{\mu} \frac{d}{dk} d_0(k).$$  \hspace{1cm} (46)

This is derived in Appendix A. Therefore, a change of gauging of $D$ (e.g., by adding staples, clover term, etc.) affects only the finite integrals (40)–(43).

A further advantage becomes apparent when considering the description of $D$ in terms of lattice paths [30,31] (we will discuss the path description more explicitly in Sec. V). It is easy to see that the vertex function $d_n(k)p_1, \ldots, p_n$ receives contributions only from lattice paths which contain a lattice link parallel to the $\mu_1$ axis, preceded at some point by a link parallel to the $\mu_2$ axis, preceded at some point by a link parallel to the $\mu_3$ axis, and so on. In particular, if the lattice paths describing $D$ are straight lines, as is the case for the Wilson-Dirac, naive and staggered operators, then $d_n(k)\mu_{\cdots}\mu_n$ vanishes unless the $\mu_j$’s are all the same. It follows that the finite terms (40)–(43) all vanish in this case (since $\mu \neq \nu$ there). Thus, for such lattice Dirac operators, $I(am)$ is given entirely by $I_{(1,1,1)}(am)$. If staples “ $\mu \nu \mu$ ” are attached to such an operator then (40)–(42) are nonvanishing while (43) still vanishes. If a clover term ($= \text{closed paths around plaquettes}$) is added then all the finite integrals (40)–(43) are potentially nonvanishing. However, as we will see in Sec. V, $d_3(k)_{\nu\mu\nu}$ and $d_4(k)_{\nu\mu\nu\nu}$ both vanish in the clover case, so the terms (42) and (43) also vanish there.

These properties make (38)–(45) useful for evaluating $I(am)$ and $c_I$ in practice for specific lattice fermion formulations, especially for improved formulations. E.g., when the improved $D$ differs from the original one by a more complicated choice of gauging the only new quantities that need to be evaluated are the finite integrals (40)–(43) with $m = 0$ in $d_0(k)$. The quantities $d_2(k)_{\mu\nu}, d_3(k)_{\nu\mu\nu}$, and $d_4(k)_{\nu\mu\nu\nu}$ appearing in their integrands are generally easy to determine in practice as we will see in Sec. V. Besides these, the integrands only involve the free fermion $d_0(k)$ and its derivative [recall (46)].

Taking the initial formula for $I(am)$ in this section as starting point, we go on to derive more explicit expressions in the following two sections.

**IV. Formulas For $I_{(1,1,1)}(am)$**

For simplicity we use the notations $d_0 = d_0(k)$ and $\partial_\mu = \frac{\partial}{\partial x^\mu}$ in the following. We assume that

$$\Delta_0 = \frac{d_0^\dagger d_0}{\Delta_0} = d_0 d_0^\dagger$$  \hspace{1cm} (47)

is a scalar, i.e., trivial in spinor space. Note that this is a free field statement; it holds for all lattice Dirac operators of current interest (naive, staggered, Wilson, overlap, . . .).

Recalling (46): $d_I(k)_\mu = -i\partial_\mu d_0$, and using the relations

$$d_0^{-1} = \frac{d_0^\dagger}{\Delta_0}, \quad \partial_\mu d_0^{-1} = \frac{1}{\Delta_0} \left( \partial_\mu d_0^\dagger \frac{\partial d_0}{\partial_\mu} \right).$$  \hspace{1cm} (48)

evaluation of (39) leads to

$$I_{(1,1,1)}(am) = \frac{1}{24 \pi} \int_{-\pi}^{\pi} d^4k \frac{\text{tr}X_{\nu\nu}(k)}{\Delta_0(k)^2}$$  \hspace{1cm} (49)

for any choice of $\mu, \nu$ with $\mu \neq \nu$, where

$$X_{\nu\nu} = -6d_0^\dagger \partial_\nu d_0 \partial_\nu d_0^\dagger \partial_\nu d_0 + 2\tilde{\partial}_\nu \Delta_0 \partial_\nu d_0^\dagger \partial_\nu d_0$$

$$- 2\tilde{\partial}_\nu \Delta_0 \partial_\nu d_0^\dagger \partial_\nu d_0.$$  \hspace{1cm} (50)

The details of the calculation are given in Appendix B. To evaluate this expression further, we now assume that $d_0$ (the free field momentum representation of the lattice Dirac operator $D$) has the general form

$$d_0 = i\gamma_\sigma \rho_\sigma + \lambda$$  \hspace{1cm} (51)

where $\rho_\sigma(k)$ and $\lambda(k)$ (which includes the mass term) are real scalar functions, and the gamma-matrices are Hermitian, so that $d_0^\dagger = -i\gamma_\sigma \rho_\sigma + \lambda$ and $\Delta_0 = \rho^2 + \lambda^2$. This is the typical free field form of lattice Dirac operators of interest in practice; it covers the naive, staggered, Wilson, and overlap operators and their improved versions. For simplicity we make the further assumption that

$$\partial_\mu \partial_\nu d_0 = 0 \quad \text{for} \quad \mu \neq \nu.$$  \hspace{1cm} (52)

This holds for Wilson, naive, and staggered fermions, also when the Naik term is included, but does not hold for the overlap operator. (The extension of the following to the general case $\partial_\mu \partial_\nu d_0 \neq 0$ is straightforward but tedious, and we defer it to a future article where the specific results for the overlap operator will be derived.)

Substituting (51) into (49) and (50), a calculation using (52) and the other mentioned properties gives...
The invariance of ons [32], fermion decomposes into four degenerate staggered fermions. (Recall from Sec. III that for a staggered fermion). This is precisely the expression the calculations in Appendix B), a more compact expression can be obtained

\[
I_{(1,1,1,1)}(am) = -\int_{-\pi}^{\pi} \frac{d^4k}{(2\pi)^4} \left[ \frac{Y_{\mu\nu}(k)}{\Delta_0^2} \right] - \frac{1}{2} (\partial_\mu \partial_\nu \log \Delta_0)^2 \right] \]  
(54)

(recall \(\Delta_0 = \rho^2 + \lambda^2\)). Although this expression is more compact, the preceding one (53) and (54) seems more useful for evaluating \(I_{(1,1,1,1)}(am)\) in practice.

In the remainder of this section we show that these general formulas readily reproduce the previously known results for the specific cases of (unimproved) naive, staggered, and Wilson fermions. (Recall from Sec. III that \(I(am)\) is given entirely by \(I_{(1,1,1,1)}(am)\) in these cases.)

A. Naive and staggered fermions

For a naive fermion, \(\rho_\sigma = \sin k_\sigma, \lambda = am\), and (54) reduces to

\[
Y_{\mu\nu}(k) = 4 \cos^2 k_\mu \cos^2 k_\nu \cos^2 k_\nu \]  
(56)

up to terms which are \(O(a)\) for \(a \to 0\). Since a naive fermion decomposes into four degenerate staggered fermions [32], \(I(am)\) for a staggered fermion is obtained by dividing the naive fermion result by four. The invariance of (56) under \(k_\sigma \to k_\sigma + \pi\) allows the integration domain in (53) to be restricted to \([-\pi/2, \pi/2]^4\) at the expense of an overall factor of 16. Thus we find

\[
I(am) = N_i \int_{-\pi/2}^{\pi/2} \frac{d^4k}{(2\pi)^4} \left[ \frac{1}{\cos^2 k_\mu \cos^2 k_\nu - \cos^2 k_\mu \cos^2 k_\nu} \right] \]  
(57)

up to terms which vanish for \(a \to 0\), where \(N_i\) is the number of fermion “tastes” (16 for a naive fermion, 4 for a staggered fermion). This is precisely the expression for \(I(am)\) derived previously in Eq. (6.8) of [12] where the contribution to the gluonic two-point function from a naive/staggered fermion loop was evaluated. \([I(am)\) corresponds to \(\Pi'/10\) in [12].]

After changing variables by \(k_\sigma \to k_\sigma/2\) the integral (57) can be evaluated by the method of Ref. [23]. It expresses the integral in terms of certain basic lattice integrals that were evaluated numerically to high precision in [23]. We find the following result:

\[
I(am) = N_i \left[ \frac{1}{24 \pi^2} (\log(2\lambda)^2 + \gamma_E - F_0) + \frac{7}{144} Z_0 \right] \]  
(58)

where \(\gamma_E\) is the Euler constant and \(F_0, Z_0\) are numerical constants listed to high numerical accuracy in Table 1 of [23]. Thus the divergent part has the correct universal structure, and the constant \(c_l (= -l_0^0)\) that we are after is given by

\[
-c_l/N_i = \frac{1}{24 \pi^2} (F_0 - \gamma_E - \log(4)) - \frac{7}{144} Z_0 \]  
(59)

In Ref. [12] this constant was denoted \(P_4\) and our value agrees with the one in Eq. (6.16) of that paper. We have obtained it to much higher numerical precision here though, thanks to the high accuracy to which \(F_0\) and \(Z_0\) were evaluated in [23].

B. Wilson fermions

In this case \(\rho_\sigma = \sin k_\sigma, \lambda = r \sum_\alpha (1 - \cos k_\sigma) + am\) where \(r\) is the Wilson parameter, and (54) reduces to

\[
Y_{\mu\nu}(k) = 4 \cos^2 k_\mu \cos^2 k_\nu \cos^2 k_\nu \]  
(60)

up to terms which are \(O(a)\) for \(a \to 0\). Substituting this into (53) we recover the previous result of Kawai et al. for the one fermion loop contribution in Eq. (3.24)–(3.25) of Ref. [10]. [Dimensional regularization of the infrared divergence was used there, but the result is easily transformed into mass-regularized form (cf. Sec. 5.1 of [23]) and then coincides with ours.] The constant \(c_l\) is related to the constant \(L\) defined there by

\[
c_l = \frac{1}{24 \pi^2} (\gamma_E - \log(4\pi)) + \frac{1}{2} L. \]  
(61)

The integral \(I(am)\) can again be evaluated by the method of
Ref. [23]; in fact this was done in that paper for \( r = 1 \), and the expression for \( L \) in terms of the basic constants is given in Eq. (6.8) of [23]. From that, \( l_0' \) is obtained to high precision in the Wilson fermion case

\[
l_0' = -c_1 = 0.00669599933173308 \ldots
\]  

(62)

The Wilson fermion case was also considered independently by P. Weisz in [11]. Note that for Wilson fermions \((\partial_\mu \rho_\rho)^2 + (\partial_\mu \lambda)^2 = \sin^2 k_\mu + \cos^2 k_\mu = 1\), hence (55) simplifies to

\[
I(am) = -\frac{1}{\Delta_0} \left( \frac{1}{2} \frac{1}{\Delta_0^2} - \frac{1}{\Delta_0^2} \right)
\]  

(63)

thus reproducing Weisz's expression in Eq. (13) of [11].

The constant \( l_0' \), denoted as \( P_3 \) there, was evaluated numerically but to low precision—a systematic error of \( \approx 2\% \) was estimated, and this is indeed the case when comparing the value for \( P_3 \) in Eq. (22) of [11] with the high precision value in (62) above.

### V. EVALUATION OF THE FINITE INTEGRALS

In this section we derive general formulas for the finite integrals (40)–(43) and describe how these can be straightforwardly evaluated, using staple and clover terms as illustrations.

**Evaluation of \( I_{0,1,2}(am) \):** Starting from (40), calculations of the same type as in Appendix B lead to

\[
I_{0,1,2}(am) = -\int_{-\pi}^{\pi} \frac{d^4 k}{(2\pi)^4} \frac{4(\rho_\mu \partial_\mu \partial_\nu \partial_\rho \partial_\rho \lambda + \rho_\nu \partial_\mu \partial_\mu \partial_\nu \partial_\rho \lambda - \partial_\mu \partial_\nu \partial_\rho \partial_\rho \lambda) e_{\mu \nu}}{(\rho^2 + \lambda^2)^2}
\]  

(66)

(There are no terms involving derivatives of \( e_{\mu \nu}(k) \) since these all cancel out.)

**Evaluation of \( I_{0,2}(am) \):** From (41) we obtain

\[
I_{0,2}(am) = \int_{-\pi}^{\pi} \frac{d^4 k}{(2\pi)^4} \frac{I_{0,2}(am)}{\Delta_0^2}
\]  

(67)

Specializing as before, this leads to

\[
I_{0,2}(am) = -2 \int_{-\pi}^{\pi} \frac{d^4 k}{(2\pi)^4} \frac{\lambda^2 \rho_{\mu \nu}^2}{(\rho^2 + \lambda^2)^2}
\]  

(68)

**Evaluation of \( I_{0,1,3}(am) \):** From (42) we find

\[
I_{0,1,3}(am) = \int_{-\pi}^{\pi} \frac{d^4 k}{(2\pi)^4} \frac{I_{0,1,3}(am)}{\Delta_0^2}
\]  

(69)

with the notation \( d_{3\chi} = d_3(\chi) \). Specializing as before, and assuming that \( d_{3\chi} \) has the general form

\[
d_3(\chi) e_{\chi \nu} = \gamma_\chi e_{\nu} - i f_{\nu}
\]  

(70)

leads to

\[
I_{0,1,3}(am) = \int_{-\pi}^{\pi} \frac{d^4 k}{(2\pi)^4} \frac{\rho_\mu \partial_\nu e_{\nu} + \lambda \partial_\mu e_{\nu}}{\rho^2 + \lambda^2}
\]  

(71)

**Evaluation of \( I_{0,4}(am) \):** From (43) we find

\[
I_{0,4}(am) = -\int_{-\pi}^{\pi} \frac{d^4 k}{(2\pi)^4} \frac{I_{0,4}(am)}{\Delta_0^2}
\]  

(72)

with the notation \( d_{4\chi} = d_4(\chi) \). A specialized formula can be worked out as in the previous cases (we omit the details). Note that terms in \( d_{4\chi} \) involving a product of two or more gamma matrices give vanishing contribution to the trace in (72).

To evaluate the integrals in practice one needs to determine \( d_2(\chi) \), \( d_3(\chi) \), and \( d_4(\chi) \) for the lattice Dirac operator \( D \). This can be done straightforwardly from the description of \( D \) in terms of lattice paths, as we now describe. In the path description, \( D \) is expressed as

\[
D\psi(x) = \frac{1}{a} \sum_\chi c_\chi \Gamma_\chi U_\chi[x, x + a\Delta \chi] \psi(x + a\Delta \chi)
\]  

(73)

where the sum is over a collection of translation-equivalence classes \( \mathcal{P} \) of oriented lattice paths. Each has an associated numerical constant \( c_\chi \) and element \( \Gamma_\chi \) of the Clifford algebra generated by the gamma matrices. Associated with each equivalence class \( \mathcal{P} \) is a vector \( \Delta \chi \) with integer components: it is the difference in lattice units between the start and end points. \( U_\chi[x, x + a\Delta \chi] \) denotes
the product of the link variables along the representative path for \( P \) starting at \( x + a \Delta_P \) and ending at \( x \). The Clifford algebra-valued functions \( d_n(k)_{\mu_1 \cdots \mu_n} \) in the expansion (26) and (27) of \( D \) are found by expanding the link variable products \( U_P[x, x + a \Delta_P] \) in (73) in powers of the continuum gauge field \( A \). In the present case we only need to determine these functions at vanishing “external momenta,” i.e., \( d_n(k)_{\mu_1 \cdots \mu_n} = d_n(0, \ldots, 0)_{\mu_1 \cdots \mu_n} \). Therefore we can take the continuum gauge fields \( \{ A_{\mu} \} \) to be constants. Then \( U_P[x, x + a \Delta_P] \) is independent of \( x \), and its expansion in powers of the continuum gauge field has the form

\[
U_P = \sum_n P_{\mu_1 \cdots \mu_n} A_{\mu_1} \cdots A_{\mu_n}.
\] (74)

The functions \( d_n(k)_{\mu_1 \cdots \mu_n} \) are then given by

\[
d_n(k)_{\mu_1 \cdots \mu_n} = \sum P_{\mu_1 \cdots \mu_n} e^{i \Delta_P \cdot k}.
\] (75)

Thus, given the description (73) of \( D \) in terms of lattice paths, the problem of determining \( d_n(k)_{\mu_1 \cdots \mu_n} \) is reduced to determining the coefficients \( u_{\mu_1 \cdots \mu_n} \) in the expansion (74) of the link variable product \( U_P \) with constant \( A \), which is generally straightforward in practice. In the present case things are further simplified since we only need to know \( d_n(k)_{\mu_1 \cdots \mu_n} \) when \( \mu_1 \cdots \mu_n = \mu \nu, \nu \mu \nu \), and \( \mu \nu \mu \nu \). Since \( \mu \neq \nu \) we can replace each link variable \( U^{\pm 1}_{\sigma} \) appearing in the product \( U_P \) by

\[
U^{\pm 1}_{\sigma} \rightarrow \begin{cases} 
1 \pm A_{\sigma} & \text{if } \sigma \in \{ \mu, \nu \} \\
1 & \text{if } \sigma \notin \{ \mu, \nu \}. 
\end{cases}
\] (77)

To illustrate this, consider the case of a “ \( \nu \mu \nu \) staple” \( U_P = U_\nu U_\mu U_\nu^{-1} \). The relevant parts of the expansion are found by

\[
U_\nu U_\mu U_\nu^{-1} \rightarrow (1 + A_\nu)(1 + A_\mu)(1 - A_\nu) = -A_\mu A_\mu A_\nu + \text{other}
\] (78)

where “other” refers to terms which are not proportional to \( A_\mu A_\nu, A_\nu A_\mu A_\nu, \) or \( A_\lambda A_\mu A_\nu \), and therefore do not contribute to \( d_2(k)_{\mu \nu}, d_3(k)_{\nu \mu \nu}, \) or \( d_4(k)_{\mu \nu \mu \nu} \). Thus the relevant contributions from the staple are

\[
d_2^P(k)_{\mu \nu} = -c_P \Gamma_P e^{i k_\nu}, \quad d_3^P(k)_{\nu \mu \nu} = -c_P \Gamma_P e^{i k_\nu}, \quad d_4^P(k)_{\mu \nu \mu \nu} = 0
\]

where \( c_P \Gamma_P \) are whatever factors that accompany the staple \( U_P \) in the expression (73) for the lattice Dirac operator.

As another example we now consider the Sheikholeslami-Wohlert (SW) clover term for Wilson clover fermions [21]

\[
C = c_{sw} \frac{i}{4} \sum_{\alpha \beta} \sigma_{\alpha \beta} P_{\alpha \beta}
\] (80)

where \( c_{sw} \) is a tunable constant, \( \sigma_{\alpha \beta} = \frac{1}{2} [\gamma_\mu, \gamma_\nu] \), and \( P_{\alpha \beta}(x) \) is a sum of products of link variables around oriented plaquettes in the \( \alpha \beta \) plane starting and ending at \( x \). The relevant contributions in this case come from the \( \alpha \beta \) parts

\[
c_{sw} \frac{i}{4}(\sigma_{\mu \nu} P_{\mu \nu} + \sigma_{\nu \mu} P_{\nu \mu}) = -c_{sw} \frac{1}{2} \gamma_\mu \gamma_\nu P_{\mu \nu}.
\] (81)

For constant gauge fields, \( P_{\mu \nu} \) is explicitly given by

\[
P_{\mu \nu} = \frac{1}{8} [U_\mu U_\mu U_\mu^{-1} U_\nu U_\nu^{-1} U_\nu^{-1} - U_\mu^{-1} U_\nu U_\mu + U_\mu^{-1} U_\mu U_\nu U_\mu^{-1} - \mu \leftrightarrow \nu].
\]

(82)

Expanding this as described above, the relevant expansion coefficients are found to be \( u_{\mu \nu} = 1, u_{\nu \mu \nu} = 0, \) and \( u_{\mu \nu \mu \nu} = 0 \). Since the plaquette paths are closed we have \( \Delta_P = 0 \) in all cases. Using this, it follows from (75) and (76) that

\[
d_2(k)_{\mu \nu} = -c_{sw} \frac{1}{2} \gamma_\mu \gamma_\nu, \quad d_3(k)_{\nu \mu \nu} = 0, \quad d_4(k)_{\mu \nu \mu \nu} = 0
\]

(83)

independent of \( k \). Note that, as discussed in Sec. III, there are no contributions from the Wilson-Dirac operator since in its path description the paths are all straight lines.

The finite integral contributions to \( I(\alpha m) \) can now be determined in the case of Wilson clover fermions. By (83) and the previous formulas, \( I_{(1,3)} = I_{(0,4)} = 0 \). The other integrals are determined by substituting \( \rho_{\mu} = \sin k_{\mu}, \lambda = r \sum_{\sigma}(1 - \cos k_{\sigma}) + am \), and \( \epsilon_{\mu \nu} = -c_{sw}/2 \) into (60) and (68). Taking the Wilson parameter to be \( r = 1 \) and evaluating the integrals by the method of Ref. [23] we find, in the \( a \to 0 \) limit,

\[
I_{(1,1,2)}(0)/c_{sw} = \frac{i}{8} F(1, 0) - F(2, -1)
\]

\[
= 0.005 046 714 052 535 753 066 \ldots
\] (84)

and

\[
I_{(2,2)}(0)/c_{sw}^2 = -\frac{1}{8} F(2, -2)
\]

\[
= -0.029 843 467 195 426 848 15 \ldots
\] (85)

where \( F(1, 0), F(2, -1), \) and \( F(2, -2) \) are certain basic convergent one-loop lattice integrals defined in Sec. 4 of Ref. [23], whose numerical values are given to high precision in Table 2 of that paper.

Recalling (45), collecting the results for Wilson clover fermions with \( r = 1 \) we have

\[
l_0 = c_4 = (62) - c_{sw}(84) - c_{sw}^2/(85)
\]

(86)

[62] means the numerical constant given in Eq. (62), etc.] This agrees with the previous literature but gives the nu-
herical constants to much greater precision. The previously most precise values were those in Eq. (14) of Ref. [17] where (84) and (85) were given to 11 decimal places. We have obtained them here to 20 decimal places, thanks to the high precision with which the basic integrals in Ref. [23] were evaluated. For earlier results for these quantities, see [4] and the references therein.

VI. CONCLUDING REMARKS

The focus in this paper has been on deriving the general integral formulas for \( I(\text{am}) \), confirming their correctness by checking that they reproduce the known results in the cases of staggered, Wilson, and clover fermions, and in the process developing general techniques for evaluating the formulas. In doing this we were able to express \( I(\text{am}) \) in those cases in terms of basic one-loop lattice integrals that have already been evaluated to high precision in [23]. This had already been done in [23] in the Wilson fermion case, but the results for the staggered and clover cases [(59), (84), and (85), respectively] are presented here for the first time. The further applications of the general formulas are left for future work, and in the following we discuss some possibilities for this.

Obvious targets for future applications are the various improved versions of staggered fermions. These formulations involve “smearing” of the link variables to reduce flavor symmetry violations; specifically there is the “Fat-7” link [33] and hypercube smeared (HYP) link [34]. Since these differ from unimproved staggered fermions only by a choice of gauging, evaluating \( I(\text{am}) \) should be straightforward: expand the relevant products of link variables in powers of the constant continuum gauge field to determine \( d_2(k)_{\mu\nu} \), \( d_3(k)_{\mu\nu\rho} \), and \( d_4(k)_{\mu\nu\rho\sigma} \) as described in Sec. V; then, from the formulas in Sec. V the convergent integrals \( I_{1(1,1,2)}, I_{2(2,2)}, I_{1(1,3)}, \) and \( I_{0(0,0)} \) can be explicitly evaluated by the method of Ref. [23]; this will express the integrals in terms of basic lattice integrals that have already been calculated to high precision. Adding these to the already known \( I_{1(1,1,1)}(\text{am}) \) \( [ = I(\text{am}) \) for unimproved staggered fermions] then gives \( I(\text{am}) \) in these improved cases.

Of more interest, however, is the case of \( O(\alpha^2) \) improved “Asqtad” staggered fermions [24] that are currently used by the MILC collaboration to generate the ensembles used in high precision lattice simulations [35]. Besides smearing of link variables, this formulation also contains the Naik term [22] which modifies the free field staggered Dirac operator. Therefore, \( I_{1(1,1,1)} \) is not the same as for unimproved staggered fermions in this case, and the method and results of Ref. [23] do not apply. \( I(\text{am}) \) may still be readily determined in this case from the general formulas and techniques of this paper, but it will be necessary to numerically evaluate the one-loop lattice integrals that arise. (The approach of Ref. [36] could be used for this.) The relation between the \( \overline{M}_S \) coupling and bare lattice coupling has already been determined to two loops for Asqtad staggered fermions via a symbolic computer program [2]. Determining the fermionic contribution to the one-loop coefficient independently via the (semi-)analytic approach of the present paper would provide a useful check on the computer program.

Another future application is to overlap fermions. The fermionic contribution to the one-loop relation between the \( \overline{M}_S \) coupling and bare lattice coupling in this case was calculated via a symbolic computer program in [13], and the two-loop relation was subsequently calculated in [18,19]. Application of the results of the present paper will allow the one fermion loop contribution to be obtained from numerical evaluation of one-loop lattice integrals without the need for symbolic computer programs. Reproducing the result of [13] in this way will be a useful check on the computer program, which the two-loop result [18,19] also relies on. It will also allow the one fermion loop contribution to be calculated more easily and to higher precision for any value of the overlap parameter that one wishes to consider. I emphasize that, in the approach of the present paper, the technical problem of calculating the one fermion loop contribution for overlap fermions is greatly reduced compared to the usual approach followed in [13]. The simplification comes about because the determination of the quantities \( d_3(k)_{\mu\nu\rho} \), \( d_3(k)_{\mu\nu\rho\sigma} \), and \( d_4(k)_{\mu\nu\rho\sigma} \), in the expansion of the overlap Dirac operator can be done with constant continuum gauge fields. Expansion of the overlap Dirac operator in powers of constant continuum gauge fields is relatively straightforward, and has already been successfully used [37] to reproduce results obtained via a symbolic computer program in another context [38].

Having found useful general formulas for the fermionic contribution to the coefficient in the one-loop relation between the \( \overline{M}_S \) and bare lattice couplings, a natural question is whether a similar approach is possible for the contribution from the gauge and ghost loops. In fact this seems quite possible. In the background field approach the gauge field in the action is \( A + gQ \), and it is the part quadratic in the quantum fluctuation fields \( Q \) that determines the one-loop contribution to the effective action. Coming from the functional integral of a quadratic term, it is clear that this can be expressed as a functional determinant, both in the continuum and lattice settings. There is also the Faddeev-Popov determinant through which the ghosts arise. One can then expand the determinants in powers of \( A \) as done for the fermion determinant in this paper. The constant to be determined in this case, \( c_{\text{lat}}^g \) in (9), can again be found from the quartic term in the expansion (via Ward identities). In the fermionic case considered in the present paper, the possibility to introduce an infrared regulator mass was crucial for deriving the general formulas. This can also be done in the gluonic-ghost case: note

\[ \text{Reference [37] is the work mentioned in the concluding section of [38].} \]
that $Q$ transforms under gauge transformations by $Q \rightarrow UQU^{-1}$ so a regulator mass term $m r Q^2$ may be introduced without breaking gauge invariance. This is currently being pursued, and I hope to be able to present general formulas for the gluonic-ghost contribution to the one-loop coefficient in future work. The hope is that this may allow a (semi-)analytic calculation of the one-loop contribution in the case of improved lattice gauge actions, which has recently been evaluated via a symbolic computer program in [14].

Finally, the results of this paper are relevant for a previous proposal for constructing the gauge field action on the lattice from the lattice fermion determinant [26]. Set $\eta = am$ and regard $m = \eta/a$ as a function of $\eta$ and $a$. Expanding $\Gamma_{\text{det}}(p_1, \ldots, p_{n-1})_{\mu_1 \cdots \mu_n}$ in (33) in powers of the momenta, without taking the $a \rightarrow 0$ limit, leads on dimensional grounds to the following variant of (34)

$$\log \det D(\eta) - \log \det D_0(\eta) = -I(\eta)S_{YM}(A) + \sum_{r \in \mathbb{C}} \alpha^r S_r(A, \eta)$$

where $S_r(A, \eta)$, a function of $A$ and $\eta$, has mass-dimension $r$. Now taking $a \rightarrow 0$ we obtain

$$\lim_{a \rightarrow 0} (\log \det D(\eta) - \log \det D_0(\eta)) = -I(\eta)S_{YM}(A).$$

(Strictly speaking this depends on the sum in (87) being convergent, which requires the continuum gauge field $A$ to be sufficiently weak.) Thus the coefficient of the YM gauge action obtained from the lattice fermion determinant is seen to be $-I(\eta)$, which can be evaluated from the general formulas in this paper after replacing $a m$ by $\eta$. In the $a \rightarrow 0$ limit we have

$$I(\eta) = -\frac{1}{24\pi^2} \log(\eta^2) + c_1.$$  

Although calculation of the constant $c_1$ was the main focus in this paper, the general formulas can just as well be used to determine $I(\eta)$ for general values of $\eta$. The integrals will need to be evaluated numerically for the specific values of $\eta$ that one considers though.

**ACKNOWLEDGMENTS**

I am very grateful to Professor Peter Weisz for his constructive suggestions on the previous (and completely different) version of this paper. At S.N.U. the author is supported by the BK21 program. At F.I.U. the author was supported under NSF Grant No. PHY-0400402. Some of this work was done during the KITP program “Modern Challenges for Lattice Field Theory” where the author was supported under NSF Grant No. PHY99-0794.

**APPENDIX A: DERIVATION OF FORMULA (46) FOR $d_1(k)_\mu$**

We derive this from the path description (73)–(76) of the lattice Dirac operator. From (76) we have

$$d_0^r(k) = c_2 \Gamma p e^{i \Delta r^\mu}$$

$$d_1^r(k)_\mu = c_2 \Gamma p u^\mu_r e^{i \Delta r^\mu}.$$  

Thus to show the relation (46): $d_1(k)_\mu = -i \partial_\mu d_0(k)$ it suffices to show

$$u^\mu_r = (\Delta^\mu_r).$$

From the definition (74) it is easy to see that $u^\mu_r$ counts the number of links of the path $P$ that lie along the $\mu$ direction, counted with the sign $\pm$ depending on whether they are oriented in the positive or negative $\mu$ direction. But this is precisely the $\mu$ coordinate of the difference (in lattice units) between the start and end points of (a representative path for) $P$, i.e., the $\mu$ coordinate of $\Delta_r$. Thus we have found that (A3) holds.

**APPENDIX B: DERIVATION OF THE GENERAL FORMULA FOR $I_{[1,1,1,1]}(am)$**

The general formula (49) and (50) is obtained by evaluating the integrand in the initial expression (39) as follows. For notational simplicity we omit the “$\mu$” write $\Delta$ for $\Delta_0$, $\Delta_1$, and use “$\equiv$” to denote equality up to terms which vanish upon taking the trace or terms which are total derivatives and therefore give vanishing contribution to the integral

$$d^r \partial_\mu d^{-1} \partial_\nu d^{-1} \partial_\rho d^{-1} \partial_\sigma d = \partial_\mu d^{-1} \partial_\nu d \partial_\rho d^{-1} \partial_\sigma d \equiv \frac{1}{\Delta^2} \partial_\mu d^{-1} \partial_\nu d \partial_\rho d^{-1} \partial_\sigma d$$

$$\Delta \equiv \frac{1}{\Delta^2} \partial_\mu d^{-1} \partial_\nu d \partial_\rho d^{-1} \partial_\sigma d + \partial_\mu \left( \frac{1}{\Delta^2} d^{-1} \partial_\nu d \partial_\rho d^{-1} \partial_\sigma d \right)$$

$$\Delta \equiv \frac{1}{\Delta^2} d^{-1} \partial_\mu \left( \partial_\nu d \partial_\rho d^{-1} \partial_\sigma d \right) + \partial_\mu \left( \frac{1}{\Delta^2} d^{-1} \partial_\nu d \partial_\rho d^{-1} \partial_\sigma d \right).$$  

The second term here is reexpressed using

$$d^r \partial_\nu d \partial_\rho d \partial_\sigma d \equiv \left( \partial_\nu - \partial_\nu d \partial_\rho d^{-1} \partial_\sigma d \right)$$

$$= \partial_\nu \Delta \partial_\nu d - \Delta \partial_\nu d \partial_\nu d$$  

(B2)
to get
\[
\frac{1}{3} \partial_\nu \left( \frac{-1}{2\Delta^2} \partial_\mu^2 \Delta d \partial_\nu d - \frac{1}{3\Delta^2} \partial_\mu^2 \Delta \partial_\nu d \partial_\nu d \right)
\]
\[
\approx \frac{1}{3\Delta^2} \left( \frac{1}{2} \partial_\nu (\partial_\mu^2 \Delta d \partial_\nu d) - \partial_\mu^2 \partial_\nu d \partial_\nu d \right)
\]
(B3)

The third term in (B1) is reexpressed as
\[
\frac{1}{3} \partial_\nu \left( \frac{-1}{2\Delta^2} \partial_\mu^2 \Delta d \partial_\nu d \partial_\nu d \right)
\]
\[
\approx \frac{1}{6\Delta^2} \partial_\mu^2 (d \partial_\nu d \partial_\nu d \partial_\nu d)
\]
(B4)

The resulting expression for the integrand, given by the first term in (B1) plus (B3) plus (B4), leads to the claimed formula (49) and (50).
