mHealth adoption in low-resource environments: A review of the use of mobile healthcare in developing countries

Abstract
The acknowledged potential of using mobile phones for improving healthcare in low-resource environments of developing countries has yet to translate into significant mHealth policy investment. The low uptake of mHealth in policy agendas may stem from a lack of evidence of the scalable, sustainable impact on health indicators. The mHealth literature in low- and middle-income countries reveals a burgeoning body of knowledge; yet existing reviews suggest that the projects yields mixed results. This paper adopts a stage-based approach to understand the varied contributions to mHealth research. The heuristic of input-mechanism-outputs is proposed as a tool to categorize mHealth studies.

This review (63 papers comprising 53 studies) reveals that mHealth studies in developing countries tend to concentrate on specific stages, principally on pilot projects that adopt a deterministic approach to technological inputs \([n=2]\), namely introduction and implementation. Somewhat less studied research designs that demonstrate evidence of outputs \([n=15]\), such as improvements in healthcare processes and public health indicators. The review finds a lack of emphasis on studies that provide theoretical understanding of adoption and appropriation of technological introduction that produces measurable health outcomes. As a result, there is a lack of dominant theory, or measures of outputs relevant to making policy decisions. Future work needs to aim for establishing theoretical and measurement standards, particularly from social scientific perspectives, in collaboration with researchers from the domains of information technology and public health. Priorities should be
set for investments and guidance in evaluation disseminated by the scientific community to practitioners and policymakers.

**Background**

*Introduction*

The growing evidence for the use of mobile information and communication technologies and mobility of information in healthcare (called mobile health or mHealth) has attracted the attention of practitioners, researchers and policymakers globally (Free et al., 2010; Leslie, Sherrington, Dicks, Gray, & Chang, 2011; Vodafone, 2006; Waegemann, 2010). Mobile phones have the potential to revolutionize healthcare, particularly in low-resource settings of low- and middle-income countries where healthcare infrastructure and services are often insufficient (Kahn, Yang, & Kahn, 2010).

Pilot mHealth projects have shown that, particularly in developing countries, mobile phones improve communication and information-delivery and –retrieval processes over vast distances between healthcare service providers and patients (Tamrat & Kachnowski, 2012). Mobiles provide remote access to healthcare facilities, facilitate trainings for, and consultations among, health workers, and allow for remote monitoring and surveillance to improve public health programs. This phenomenon has the potential to lead to an overall increase in the efficiency and effectiveness of under-resourced health infrastructures, ultimately translating into benefits for patients (Bloch, 2010; Ranck, 2011).

In general, however, the scalability of mHealth projects from pilot projects to large-scale nationwide implantation has been low, (Ping, Wu, Yu, & Xiao, 2006; WHO, 2011b) with the available evidence proving insufficient to persuade key
policymakers and health practitioners (Mechael et al., 2010). Amongst the reasons for this state of affairs are firstly, the lack of an ample evidence base, which is understandable for a nascent discipline; secondly, a lack of clarity in organizing the evidence to distinguish particular investigative approaches to mHealth, chief amongst which are the broad domains of technology development, social science, and public health. To resolve these issues, this paper aims to investigate prior mHealth reviews and conduct a comprehensive literature review, organizing the studies in a logical framework. In the next paragraph of this Background section we will provide an overview of the prior mHealth reviews, and then in the Methods and Results section of this paper we will describe the assessment of individual studies.

Review of literature

Recent reviews of mHealth provide a range of analyses focusing on particular technological features, process improvements in healthcare service delivery, and behaviour change and healthcare outcomes. As background to this review, we examine these mHealth reviews, noting the number of studies included in brackets [n] as a measure of scope.

The mHealth literature focusing on developing countries has certainly flourished in recent years. While the mHealth field may no longer comprehensively suffer from Kaplan’s (2006) accusation of having “almost no literature on using mobile telephones as a healthcare intervention [in developing countries]” ; also see SMS literature cited below); more recent reviews point to similar concerns (Gurman, Rubin, & Roess, 2012) [n=16]; (Mechael, et al., 2010) [n=145])

From a thematic perspective, overview studies and reviews of mHealth globally have developed lists of notable technological features of project implementation
A sub-set of mHealth reviews focus on SMS (Short Message Service), or mobile texting; yet find little rigorous evidence of effectiveness (Fjeldsoe, et al., 2009) [n=14]; (Lim, Hocking, Hellard, & Aitken, 2008) [n=9], with a few more recent studies focusing on developing countries (Cole-Lewis & Kershaw, 2010) [n=12]; (Deglise, Suggs, & Odermatt, 2012) [n=34]. Despite lack of evaluation of effectiveness, these earlier reviews suggest partial positive evidence of the impact of text messages. Recent ones are more mixed, noting both substantial (Guy et al., 2012) [n=18]; (Krishna, Boren, & Balas, 2009) [n=25], and limited, effects on improving healthcare service delivery (AuthorA, 2012a) [n=4]; (AuthorA, 2012b) [n=1], and patient care (de Tolly, Skinner, Nembaware, & Benjamin, 2012) [n=2]; (AuthorB, 2012b) [n=21]. Overall, we conclude that technology introduction and implementation and healthcare process improvements have been emphasized in the scientific literature. Less well understood in comparison are mechanisms of adoption and appropriation of technology at individual and socio-cultural levels of analysis.

Researchers have regularly called for theoretically-based interventions, suggesting the increased likelihood of meeting success criteria (Krishna, et al., 2009), yet there are few reviews that examine the role of theory in mHealth projects. A majority of the reviews chose to use methodological standards as an exclusion criteria, limiting the reviews to randomized control trials (RCTs) found within the peer-
reviewed literature, mostly upheld as the gold standard, sometimes adding experimental/quasi-experimental research designs. Others employed broader inclusion criterion, including all methodologies, as well as drawing from the grey literature.

Aim of this review

Our overview of reviews showed that though the body of mHealth knowledge is growing and studies have shown potential to improve healthcare, the current evidence is not convincing enough for policy makers. The reviews found mixed results and lack the ability to show robust evidence. The main focus of studies has been on inputs, while research in mechanism factors and underlying theory is missing. Therefore, the fundamental aim of this review is to identify, define and examine factors of inputs, mechanisms, and outputs, of mobile phones for healthcare workers and patients in low- and middle-income countries. Our objectives were to determine the relative value of research approaches within this linear model, propose recommendations that allow for collaborative research, as well as foster discussion and debate about the relative value of specific approaches to influencing practice and policy. We will do this by investigating a large number of studies, covering inputs, mechanism, and outputs, and incorporate both quantitative and qualitative evidence.

Methods

Approach

This review paper used a deductive approach addressing some of the issues outlined. First, we demarcated the boundaries of the investigation to mHealth studies conducted within developing countries, aiming, however, to cover a broader spectrum of papers than those found previously. Secondly, we focussed on all aspects, inputs, mechanism and outputs, as we argued that the investigation of the mechanisms of
adoption and appropriation of technology using social scientific methods is equally important as evidence for effective technology introduction and implementation, and public health outputs, such as process improvements and patient healthcare indicators. Finally, given the call for more nuanced methodological approaches (Mechael, et al., 2010), we broadened the review to multiple methods of investigation of the mHealth phenomenon.

We propose a pathway of research focus for mHealth studies as a heuristic within which to situate this review (Klasnja & Pratt, 2012; Thomas & Harden, 2008). We categorized the studies under the input-mechanism-outputs pathway shown in Figure 1, mapping onto a linear system of investigation within the mHealth field, which are often conflated.

Inputs include factors such as technology access and use vital to technology developers and practitioners who implement mHealth projects within beneficiary communities. Mechanism factors such as psychosocial influences and individual preferences offer explanatory value to understand technology adoption. Finally, outputs include healthcare process factors, including efficiency measures within the health system such as data-management and treatment adherence; and effectiveness measures of patient healthcare factors, defined as behaviour change or public health indicators within the beneficiary population. While the silos of technology development-social science-public health domains introduced earlier might seem to map onto this categorization simplistically, such a framework does allow for determining the relative focus of prior research investigations in the field.

**Inclusion and exclusion criteria**

We included research papers fulfilling the following inclusion criteria: those that studied the use of mobile phones in healthcare, focused on patients or healthcare
workers, and were undertaken in low-income and low- and upper- middle-income countries (as categorized by the World Bank (WorldBank, 2012)). We included both peer-reviewed and non-peer reviewed literature. We considered papers in all languages, but we only found papers in the English language. We excluded research which studied other mobile devices then mobile phones, did not focus on health or was undertaken in high-income countries.

**Review methods**

We based our methods on the Cochrane Collaboration systematic review methodology (Higgins & Green, 2011) and qualitative review methodology (Ring, Ritchie, Mandava, & Jepson, 2010; Sandelowski & Barroso, 2002; Thomas & Harden, 2008). Briefly summarized this includes defining the review question and developing criteria for inclusion and exclusion of studies, a high sensitivity search for studies, selection and data extraction using a standardised form, and considering meta-analysis when appropriate or a narrative assessment.

**Search methods**

One author (XX) used mHealth related search terms (phon*, mobil*, mhealth, m-health, ‘m health’, ehealth, telemedicine and telehealth) to search a number of electronic databases (The Cochrane Central Register of Controlled Trials (CENTRAL, The Cochrane Library, latest issue), Pubmed, EMBASE, WHO Global Health Library regional index (latest issue), PsycINFO, Web of Science, Mobile Active (http://www.mobileactive.org/), KIT Information Portal; mHealth in Low-Resource Settings (http://www.mhealthinfo.org/). The author searched the databases from October 2010 onwards as extensive searches for our previous mHealth systematic reviews (including 32,399 citations) covered the literature before this date. Reference lists of relevant studies and personal collections of articles were also searched.
Documents published before 2000 were not included as mobile phones were then not widely available in low- or middle- income countries.

One strength of this review is the extensive search of references from which selected the studies. Due to limited resources a single author undertook the review process. We acknowledge that the typology is used as a heuristic. The review is intended to be an illustration of the pathway, and not a systematic review of all mHealth studies in developing countries.

Data extraction and analysis

The author merged search results across databases, removed duplicates and screened citations against inclusion criteria. Data were extracted using a standardized form including descriptives, inputs, mechanism factors and outputs. Statistical pooling of results was not possible due to extensive heterogeneity of the study methodologies.

The papers were further categorized according to the type of the main intervention. Certain studies focussed on factors falling under more than one category; we chose to concentrate on the main intent of each study. Where studies exhibited more than one category in a significant manner, we examined the linkages.

Results

We found 53 studies (represented by 63 papers) addressing one of the three stages of the pathway, input-mechanism-outputs, shown in Figure 1. The main types of interventions studied were related to data collection (Alam, Khanam, Khan, Raihan, & Chowdhury, 2010; Andreatta, Debpuur, Danquah, & Perosky, 2011; Asiimwe et al., 2011; AuthorB, 2012a; Barrington, Wereko-Brobby, Ward, Mwafongo, & Kungulwe, 2010; Ganesan et al., 2011; Haberer, Kiwanuka, Nansera,
Wilson, & Bangsberg, 2010; Kaewkungwal et al., 2010; MOTECH, 2011; Rajatonirina et al., 2012; T. Svoronos et al., 2010) [n=11], and consultation between health workers (AuthorC, 2011b, 2012a, 2012c; Chandhanayingyong, Tangtrakulwanich, & Kiriratnikom, 2007; Chang et al., 2011; Cole-Ceesay et al., 2010; Lemay, Sullivan, Jumbe, & Perry, 2012; Macrohon & Cristobal, 2011; Skinner, Rivette, & Bloomberg, 2007; Zolfo et al., 2010; Zurovac et al., 2011) [n=11].

We categorized the papers by the main type of intervention; data collection (Alam, et al., 2010; Andreatta, et al., 2011; Asiimwe, et al., 2011; AuthorB, 2012a; Barrington, et al., 2010; Ganesan, et al., 2011; Haberer, et al., 2010; Kaewkungwal, et al., 2010; MOTECH, 2011; Rajatonirina, et al., 2012; T. Svoronos, et al., 2010) [n=11], consultation between health workers (AuthorC, 2011b, 2012a, 2012c; Chandhanayingyong, et al., 2007; Chang, et al., 2011; Cole-Ceesay, et al., 2010; Lemay, et al., 2012; Macrohon & Cristobal, 2011; Skinner, et al., 2007; Zolfo, et al., 2010; Zurovac, et al., 2011) [n=11], appointment reminders for health workers (Derenzi et al., 2012) [n=1], and patients; health promotion (AuthorC, 2012b; Danis et al., 2010; de Tolly, et al., 2012; Hamilton, 2010; Jareethum et al., 2008; L’Engle & Vadhat, 2009; K. J. Mitchell, Bull, Kiwanuka, & Ybarra, 2011) [n=7], medication reminders (Curioso et al., 2009; Walter H. Curioso & Ann E. Kurth, 2007; R. T. Lester et al., 2010; Mbuagbaw, Bonono-Momnougui, & Thabane, 2012; Pop-Eleches et al., 2011; Shet et al., 2010; Sidney et al., 2012) [n=7], appointment reminders (Chen, Fang, Chen, & Dai, 2008; Crankshaw et al., 2010; da Costa, Salomão, Martha, Pisa, & Sigulem, 2010; Kunutsor et al., 2010; Leong, Chen, & Leong, 2006; Liew et al., 2009; Prasad & Anand, 2012) [n=7], and health information for patients (Ashraf, Ansari, Tahseen Malik, & Rashid, 2010; Azfar et al., 2011; Maharani, Rosanna, & Liesman, 2012; Odigie et al., 2011; Piette et al., 2011) [n=5], test reminders
(Seidenberg et al., 2012; Wolpaw et al., 2011) \([n=2]\), while two studies did not focus on any specific intervention (Faisal, 2011; Hwabamungu & Williams, 2010).

**Inputs**

A number of studies (Alam, et al., 2010; Andreatta, et al., 2011; Asiimwe, et al., 2011; AuthorB, 2012a; AuthorC, 2012b; Azfar, et al., 2011; Barrington, et al., 2010; Chandhanayingyong, et al., 2007; Cole-Ceesay, et al., 2010; Crankshaw, et al., 2010; Curioso, et al., 2009; W. H. Curioso & A. E. Kurth, 2007; Danis, et al., 2010; Derenzi, et al., 2012; Faisal, 2011; Ganesan, et al., 2011; Haberer, et al., 2010; Kaewkungwal, et al., 2010; L’Engle & Vadhat, 2009; Lemay, et al., 2012; Macrohon & Cristobal, 2011; Maharani, et al., 2012; Mbuagbaw, et al., 2012; J. R. Mitchell et al., 2011; MOTECH, 2011; Rajatonirina, et al., 2012; Shet, et al., 2010; Sidney, et al., 2012; Skinner, et al., 2007; T. Svoronos, et al., 2010; Wolpaw, et al., 2011; Zolfo, et al., 2010) \([n, =32]\) described technological inputs required for mHealth implementation, focusing on technology access and use and on the feasibility of the intervention in terms of satisfaction, response rates, data accuracy and error rates and set-up costs. These studies were mostly pilot studies, implementation evaluations, studies with undefined design or interviews. A detailed description can be found in Table 1.

The range of technologies employed for data collection ranged from mobile applications (Alam, et al., 2010; AuthorB, 2012a; Ganesan, et al., 2011; Kaewkungwal, et al., 2010; T. Svoronos, et al., 2010), SMS-based mobile applications (Asiimwe, et al., 2011; Barrington, et al., 2010), to interactive voice calls and SMS (Haberer, et al., 2010; Rajatonirina, et al., 2012). For consultation between health workers, SMS (Lemay, et al., 2012; Macrohon & Cristobal, 2011), or MMS (Azfar, et al., 2011; Chandhanayingyong, et al., 2007) was used. Other studies used
calls and SMS for reminding patients (Wolpaw, et al., 2011), or health workers (Derenzi, et al., 2012) of their appointments, and SMS quizzes for health promotion (AuthorC, 2012b; Danis, et al., 2010), providing health information (Maharani, et al., 2012), and an application for health worker’s learning (Zolfo, et al., 2010). A diverse set of standards was applied, with no evidence provided for inter-operability.

Other studies researched the possibility of a SMS intervention for family planning (L’Engle & Vadhat, 2009), HIV prevention (J. R. Mitchell, et al., 2011), or antiretroviral therapy reminders (Curioso, et al., 2009; Mbuagbaw, et al., 2012; Shet, et al., 2010). The use of mobiles was studied in general (Faisal, 2011), for clinic appointment reminders and adherence messages (Crankshaw, et al., 2010; Shet, et al., 2010), and the use of information and communication technology in general for people living with HIV (W. H. Curioso & A. E. Kurth, 2007).

Notably, this group of studies were more relevant to practitioners, yet lacked explicit theoretical support and largely failed to address outputs. However, we found factors for technology adoption in these papers such as perceived facilitators and barriers and preferences (Alam, et al., 2010; Asiimwe, et al., 2011; AuthorB, 2012a; AuthorC, 2012b; Azfar, et al., 2011; Barrington, et al., 2010; Cole-Ceesay, et al., 2010; Crankshaw, et al., 2010; Curioso, et al., 2009; W. H. Curioso & A. E. Kurth, 2007; Derenzi, et al., 2012; Faisal, 2011; Haberer, et al., 2010; Kaewkungwal, et al., 2010; L’Engle & Vadhat, 2009; Lemay, et al., 2012; Macrohon & Cristobal, 2011; Mbuagbaw, et al., 2012; J. R. Mitchell, et al., 2011; MOTECH, 2011; Rajatonirina, et al., 2012; Shet, et al., 2010; Skinner, et al., 2007; T. Svoronos, et al., 2010; Wolpaw, et al., 2011). Some of these studies provided some evidence of potential impact (Barrington, et al., 2010; Kaewkungwal, et al., 2010; Lemay, et al., 2012; Rajatonirina, et al., 2012; T. Svoronos, et al., 2010). Two studies in rural Tanzania
showed impact: increases in the numbers of antimalarial medicines stocks (Barrington, et al., 2010), and anecdotal evidence of improved management of antenatal care (T. Svoronos, et al., 2010). A study in rural Thailand reported improved antenatal and immunization coverage (Kaewkungwal, et al., 2010).

**Mechanism**

A second and smaller number of studies (Ashraf, et al., 2010; AuthorC, 2011b, 2012a, 2012c; Hamilton, 2010; Hwabamungu & Williams, 2010) [n=6] investigated the reasons for technology adoption, using theoretical models for explanation or validation of the findings. These studies are described in detail in Table 2.

Four of these studies (AuthorC, 2012a, 2012c; Hamilton, 2010; Hwabamungu & Williams, 2010) used theory to explain the potential for mobile phones in addressing health problems. The ICT4 healthcare development model, was used by community healthcare workers for accessing information by mobile phones in rural India (AuthorC, 2012a). Castells spatio-temporal arguments (Castells, 1989) were used in rural Nepal to structure the potential of mobile phones for rural communities (AuthorC, 2012c). The Technology Acceptance Model (F. D. Davis, 1986) was adapted to study views of people living with HIV and healthcare workers on usability of mobile phone applications for healthcare in South Africa. However, the exact constructs of the theories studied were not described (Hwabamungu & Williams, 2010). Social marketing theory (Hastings, 2007) was used in rural Kenya for studying the use of mobile phones for health promotion (Hamilton, 2010).

A study in rural Indonesia (represented by five papers (AuthorC, 2008, 2009, 2010, 2011a, 2011b) evaluated an intervention wherein midwives were provided with mobile phones. Four theories were tested: the ICT4 healthcare model (Banuri, Zaidi, Spanger-Siegfried, Ali, & Zaidi, 2003) in two papers (AuthorC, 2008, 2010),
dialectical perspectives on gender (Baxter & Montgomery, 1996) in one paper (AuthorC, 2011b), the technology acceptance model (Fred D Davis, 1985) in one paper (AuthorC, 2009), and a hypothesized model of midwifes mobile phone use, access to resources, self-efficacy, and health knowledge in the last paper (AuthorC, 2011a). The communication for development framework (Bertrand, O'Reilly, Denison, Anhang, & Sweat, 2006) was used to study a health help-line in rural Bangladesh (Ashraf, et al., 2010).

A simple healthcare communication diagram (the study authors came up with this diagram) showing that patients, family, friends and healthcare workers are interconnected, was developed from studying peer health worker’s use of mobile phones to help people living with HIV to adhere to antiretroviral therapy in rural Uganda (as this study is more focussing on outputs it is categorized accordingly) (Chang, et al., 2011). The construct of stages of change (Prochaska & DiClemente, 1983) was used in a study obtaining health worker’s perspectives on receiving SMSs which aimed to improve their malaria case management (as this study is more focussing on outputs it is categorized accordingly) (Jones et al., 2012; Zurovac, et al., 2011).

We found that studies based on theory overlapped more with input studies than with outputs studies. The mechanism studies aimed to explain the adoption of technology using existing theory, or in the rare cases, advancing theory (AuthorC, 2009, 2010, 2011a). However, the selection and contextualization of some theories was questionable, since these rationales were not explicitly stated in all papers (Ashraf, et al., 2010; Hwabamungu & Williams, 2010). In three studies, the theoretical investigation concluded with an emphasis on outputs such as improved communication or greater efficiency within the healthcare system (Ashraf, et al.,
2010; AuthorC, 2011b, 2012a). All these studies showed the potential of mobile phones but apart from two (Chang, et al., 2011; Zurovac, et al., 2011), (categorized in the outputs studies) did not address quantitative impacts on healthcare.

**Outputs**

The final set of outputs studies (Chang, et al., 2011; Chen, et al., 2008; da Costa, et al., 2010; de Tolly, et al., 2012; Jareethum, et al., 2008; Kunutsor, et al., 2010; Leong, et al., 2006; R. T. Lester, et al., 2010; Liew, et al., 2009; Odigie, et al., 2011; Piette, et al., 2011; Pop-Eleches, et al., 2011; Prasad & Anand, 2012; Seidenberg, et al., 2012; Zurovac, et al., 2011) [n=15] was most relevant to policy, providing some indications of improved patient health outputs, and healthcare process improvements. Table 3 describes these studies in detail. These studies mainly used a randomized (Chen, et al., 2008; da Costa, et al., 2010; de Tolly, et al., 2012; Leong, et al., 2006; R. T. Lester, et al., 2010; Liew, et al., 2009; Pop-Eleches, et al., 2011) or cluster-randomized (Chang, et al., 2011; Zurovac, et al., 2011) controlled trial study designs.

Patient outcomes were related to medication adherence (Kunutsor, et al., 2010; R. T. Lester, et al., 2010; Pop-Eleches, et al., 2011), HIV counselling and testing (de Tolly, et al., 2012; Seidenberg, et al., 2012), HIV virology (Chang, et al., 2011; R. T. Lester, et al., 2010), mortality (Chang, et al., 2011), retention (Chang, et al., 2011), diabetes (Piette, et al., 2011), and pregnancy (Jareethum, et al., 2008). The study (represented by three papers) (Chang, et al., 2011; Chang et al., 2008; Chang et al., 2010) using the healthcare communication (described earlier in mechanism section) found no significant impact on HIV virologic outcomes, adherence to antiretroviral therapy, mortality, or retention (Chang, et al., 2011). Two randomized controlled trials in Kenya sent antiretroviral therapy reminder SMSs to people living with HIV,
and concluded that recipients significantly improved antiretroviral therapy adherence (R. T. Lester, et al., 2010; Pop-Eleches, et al., 2011), with one study (represented by four papers) (R. Lester & Karanja, 2008; R. T. Lester, Gelmon, & Plummer, 2006; R. T. Lester et al., 2009; R. T. Lester, et al., 2010) also showing improvements in HIV viral load suppression (R. T. Lester, et al., 2010). Health promotion SMSs for prenatal support found no significant differences in pregnancy outcomes in Thailand (Jareethum, et al., 2008).

Organisational outputs were reported by three randomized controlled trials (Chen, et al., 2008; Leong, et al., 2006; Liew, et al., 2009; Zurovac, et al., 2011), and other studies used varied designs (da Costa, et al., 2010; Kunutsor, et al., 2010; Odigie, et al., 2011; Prasad & Anand, 2012; Seidenberg, et al., 2012), with evidence of higher appointment attendance rates in the group receiving SMS and/or calls. A cluster randomized controlled trial represented by two papers (Jones, et al., 2012; Zurovac, et al., 2011), sent SMSs on infant malaria case-management to health workers and found that medication management by health workers improved (Jones, et al., 2012; Zurovac, et al., 2011). Four studies (Chang, et al., 2008; Chen, et al., 2008; de Tolly, et al., 2012; Leong, et al., 2006) provided information on costs, but none of the studies reported a full economic cost-effectiveness analysis.

Discussion

This review found 53 mHealth studies in developing countries: 32 input studies, six mechanism studies, and 15 outputs studies. On the one hand, it is encouraging to see the growing body of evidence related to mHealth in developing countries. On the other, it is evident that social scientific studies explicating processes of technology adoption are less emphasized within this body of research, compared to technology introduction, and improvements in healthcare process and indicators. One
result of this emphasis is the relative paucity of critical studies discussing reasons for failure, leading to stances bordering on technological determinism.

We found several gaps in the understanding of mobile interventions in healthcare, as conceptualized by the input-mechanism-outputs model, for example, of explanatory theory, and of sociological determinants of health outcomes. Few studies used theory or methodological designs (Ashraf, et al., 2010; AuthorC, 2011b, 2012a, 2012c; Hamilton, 2010; Hwabamungu & Williams, 2010), to explain why people would use mobile phones for healthcare needs, or link technological inputs to outputs (Chang, et al., 2011). When evident, a cross-disciplinary approach led to borrowing of theory from different disciplines, with no dominant theory. The behaviour-change theories utilized failed to account for context (Hwabamungu & Williams, 2010), particularly sociological factors such as culture and gender, essential for evaluating factors influencing how and why interventions work (T. Svoronos & Mate, 2011). Studies mainly utilized academically oriented measures (e.g. response rate, data accuracy) rather than measures prescribed by trans-national organizations (United Nations or the World Health Organization) such as the Millennium Development Goals indicators.

Most studies reported one or two stages of the pathway. Three studies (Chang, et al., 2011; R. T. Lester, et al., 2010; Pop-Eleches, et al., 2011) attempted to provide information on the whole pathway, but could not satisfactorily explain the theoretical mechanisms for technology adoption. Not a single study was able to provide a theoretical explanation for technology adoption that resulted in a healthcare system outcome. While it might be too early to expect comprehensive studies dealing with the complexity of linking concepts across the entire pathway, we expect mHealth
scholars to bridge disciplinary boundaries to provide such compelling evidence in the future.

Literature reviews over the past years have shown a lack of data on the effectiveness of mHealth in low- and middle-income countries in general (Blaya, Fraser, & Holt, 2010; Kaplan, 2006), and for specific purposes such as behaviour change interventions (Cole-Lewis & Kershaw, 2010; Fjeldsoe, et al., 2009), diabetes control (Liang et al., 2011), sexual health (Lim, et al., 2008), maternal healthcare (Noordam, Kuepper, Stekelenburg, & Milen, 2011; Tamrat & Kachnowski, 2012), and smoking cessation (Whittaker et al., 2009). Reported improvements of mHealth interventions on established health indicators were very limited, as were descriptions of cost-effectiveness or adverse effects. Certainly policymakers would expect greater explication of financial feasibility and mitigating factors for possible failures prior to engaging with the discipline.

The literature suggests that some projects are being scaled up to a national level without the necessary evidence from high-quality evaluation (Jordan, Ray, Johnson, & Evans, 2011; Novartis, 2011). It might be too early to do so without a systemic review of the varied mHealth initiatives. Early selection and failure of the wrong initiative, by extension of association, harms the entire field. If policymakers invest in mHealth projects, a fair amount should be reserved for evaluation purposes. Groups such as the mHealth Alliance and World Health Organisation are organizing efforts to ensure mHealth projects are guided by evidence, and avoid duplication (WHO, 2011a).

We found an encouraging growing body of knowledge about mHealth in low-resource setting of developing countries. It is, nonetheless, the appropriate time to acknowledge that the current crop of studies is not delivering the results aimed for.
Future work needs to aim for establishing technological, theoretical, and measurement standards. There is a need to consider all aspects of the input-mechanisms-outputs pathway to produce a comprehensive picture of how mobile phones can improve healthcare in low- and middle-income countries.

Researchers at the input level, primarily information technologists, need to determine the precise problems to be addressed not just from the viewpoint of technological input, but rather from both sociological and healthcare needs perspectives. Social science researchers should make choices for evaluation in terms of appropriate study design, providing clear evidence of outputs. This group should aim to make their approach relevant to technologists interested in the sociological context within which mHealth projects are conducted. Finally, public health officials need to examine the specific measures identified by policymakers for inclusion in research designs. In conclusion, an obvious recommendation is greater collaboration across disciplinary boundaries, or risk fracturing into marginalized silos. The emergent field of mHealth in developing countries is slowly gaining traction, yet can gain credibility and the confidence of practitioners and policymakers with a more organized approach to dissemination of the results. This review offers one such early attempt.

**Skinner 2007 (Cell Life program)**

- Consultation between health workers – data collection
- HIV South Africa
- Mobile pre-designed menu ‘Cell life’ for communication between therapeutic counsellors and the health services.
- Qualitative interviews
- 8 counsellors
- It was easy to learn how to use; mobiles easy to learn to use
- Improvements in technology gave additional security
- Mobile did not interfere or distract with relationship between counsellor and patient
- Improvements in technology giving additional security
- Feeling good because their work integrated them better into the community
- Having mobiles, a status item, raised status
- No feeling of pressure at being on call 24-hours-a-day and keeping the mobile on all the time
- Fear of crime as the mobile meant counsellors were more at risk for theft
- Positive impact on record keeping
- Feel more effective and secure in role due to rapid help
- Mobile phone use facilitated providing good service

**LeMay 2012**

- Consultation between health workers – data collection
- Family planning / reproductive health and HIV/AIDS
- Malawi
- SMS system to improve the exchange and use knowledge among health workers
- Baseline evaluation with quantitative and qualitative methods
- Mobile phones provided to 253 health workers, 35 focus group discussions
- A total of 1761 regular messages were sent and received
- All participating CHWs sent at least one SMS, with an average of five messages per CHW per month
- Main reasons for sending messages include reporting stock outs, asking general information, reporting emergencies, confirming meetings and requesting technical support
- Health workers with mobiles; most common modes of communication
- Health workers reported that their participation in the SMS network resulted in local recognition and improved status among their clients and communities
- Findings indicated that information exchange between the district and community levels can directly affect the quality of care patients receive

Sidney 2012: Medication adherence reminder

- Study methods: Survey
- Sample size: 139 people living with HIV
- 86% owned a phone
- Sharing a phone was associated with being female (OR 5.97; 95% CI: 2.1-17.0) or unemployed (OR 4.4; 95% CI: 1.5-13.1).
- 93% knew how to make and receive a call
- 86% knew how to receive and 47% how to send a SMS
- 744 calls were made, 545 (76%) of which were received
- All participants received the weekly pictorial SMS reminder
- 90% reported the intervention as being helpful as medication reminders, and did not feel their privacy was intruded
- 87% reported that they preferred the call as reminders, 11% preferred SMS alone
- 59% viewed all the SMSs that were delivered, 15% never viewed any at all
- No discomfort or stigma was experienced despite that other persons sometimes received the participant’s call (20%) or SMS (13%)

De-Renzi 2012: Appointment reminder health workers

- Study methods: Pilot study (1) and two (2,3) randomized controlled studies
- Sample size: 1.13 community health workers, 2.87 health workers, 3 same 87 health
- 1. Intervention: increase in ‘closed referrals’ by 33.6%; control: decrease by 34.6%
- 2. Intervention group: 86% reduction in the average number of days a community health worker’s clients were overdue (9.7 to 1.4 days); control: no significant change between baseline and after the intervention (8.2 days to 9.3 days)
- Comfortable with daily SMSs
- Personal relationships were an important factor of success, community health workers ‘understood what was happening and were comfortable enough to tell the supervisor’
- Most common reasons for overdue

| Crankshaw 2010 | | Appointment and medication adherence reminder | Urban South Africa | Survey | 300 individuals who presented for treatment at the ART clinic | No intervention. Aim: perspectives on mobiles for clinic appointment reminders and adherence messages. | -28% shared mobile with one or more other people
-87% indicated that they usually answered calls that displayed ‘private number’
-79% use of the mobile alarm function for remembering to take medication
-not were willing for the clinic to contact them on mobile either verbally (99%) or via text messages (96%)
-high mobile turnover due to theft, loss (40%) and/or damage (28%)
-33% sometimes left their mobile in a place where someone else could pick it up and access it
-25% believed that their SMSes had been read without their permission |
| Wolpaw 20110 | Test result reminder | Urban South Africa | Reminding patients who do not return for HIV test results with text messages and phone calls | Face-to-face interview | 902 high risk participants enrolled over 1 year | No intervention. Aim: perspectives on mobiles for clinic appointment reminders and adherence messages. | -40.6% came back for results
-results and counselling were delivered to 62.3% of participants and all six patients with AHI. Six (0.67%) were diagnosed with AHI. |
| Faisal 2012 | General | General Banglades | No intervention; impact assessment on existing mobile healthcare support | Surveys, telephone interviews | Ten families and 5 doctors | No intervention. Aim: perspectives on mobiles for clinic appointment reminders and adherence messages. | -90% of families had a mobile
-30% of families were aware of local mobile health services
-40% of families rely on mobile health services
-doctors receive about 10-20 calls a day
-doctors experience difficulties in diagnosing patients over the telephone but are able to provide basic advice |

-removing the ‘escalation step’, a supervisor calling the health workers, decreased performance (P= 0.023)
-preliminary costs; SMS intervention adds an estimated $0.84 USD per patient per year
-visit were that health worker was travelling, busy or forgot
-escalation; health workers were not always available when called by supervisor, local ‘champion health workers’ were used to reach them
-fewer health workers required escalation calls over time

-collective ties between the midwife for trust (94.2%) and support (83.4%).
-90.2% were heavily relied on to help in medical situations, compared to obstetrician-gynaecologists (66.6%), corresponding to the degree of satisfaction with the information gained from them (midwives, 76.7%; obstetrician-gynaecologists (63.7%).
-both midwife (91.9%) and obstetrician-gynaecologists (88.8%) are seen as fairly equal in terms of the relevancy of information that midwife seek during work.
-social contacts and written material functioned as most common modes of obtaining information, with electronic means lagging behind
-traditional methods, where accessibility, approachability and trust play a major role in shaping the efficacy of assimilating information
4.Knowledge generator
-knowledge family planning moderate, knowledge of pregnancy related issues lower, 23.9% already used the mobile phone often for obtaining relevant information 
(compared with 2.2 internet)
-90% confident to use mobile for information, 85% relevant to their needs, and 70.5% felt that it would influence the way seeking medical advice

Baseline 223 Hypothesized model of midwives’ mobile phone use, access to resources, self-efficacy, and health knowledge
1. Mobile phone use; midwives’ mobile phone use was positively associated with access to both institutional and peer-network resources
2. Access to institutional resources; access to institutional resources had a direct positive effect on midwives’ health knowledge, access to institutional resources did not increase self-efficacy
3. Access to peer resources; access to peer resources had no direct positive effect on midwives’ health knowledge, access to peer resources

3. Social enabler
-more likely to turn to health centre personnel for medical information needed (\(p=0.09\)) and access health information from the health centre using their mobiles (\(p=0.09\)).
-improved relationship across the levels of the healthcare system hierarchy
-quicker access to midwife for patients
4. Knowledge generator
-easier to search for numbers in mobile lists (\(p=0.02\)), and get the mobile to do what they wanted it to do (\(p=0.00\)).
-increased in their trust of obtaining health information from the cinema (\(p<0.06\)) and brochures (\(p=0.04\))
-medical question scores increased for standard procedures in childbirth process, decrease in medical question score (\(p<0.03\)) postpartum mother to be referred to a hospital
### Increased self-efficacy
4. **Self-efficacy:** self-efficacy was positively associated with health knowledge

### Health knowledge

</thead>
</table>

#### 1. Context
1. Distance barrier
2. Financial barrier
3. Language barrier
4. Lack of knowledgeable doctors
5. Lack of 24 hour service.
6. Lack of Health Care

#### 2. Changes in Behavioural Precursors:
1. Changes in knowledge and behaviour of both doctors and patients.
2. More positive attitude of doctors and patients.
3. Reduction of distance and other barriers

#### 3. Changes in Behaviour:
1. Increase in awareness level
2. An efficient alternative for emergency treatment
3. More relief patients

#### 4. Broader development impact:
1. An effective data base for research
2. An important tool for implementing millennium development goals
3. Efficient management and administration

Lester 2009
Lester 2008
Lester 2010
Description of crisis situation
Randomized controlled trial

Patients initiating ART, 273 received the intervention, and 265 standard care

- acceptance: 181 of 191 patients in the intervention group reported they would like the SMS programme to continue, of whom 188 (98%) said they would recommend it to a friend
- many patients in the intervention group also reported that they thought the SMS support service was valuable
- nurses were able to connect patients to new dispensaries
- support for emotional distressed patient whose home had been burned during previous
- three patients losing mobile phones
- access denied to air time "top up" by poor security or economic fallout or were forced to remain in remote areas without network coverage
- forwarding weekly SMSs to non-intervention participants to share support

Adherence to ART reported in 168 of 273 patients receiving the SMS intervention compared with 132 of 265 in the control group (RR for non-adherence 0.81, 95% CI 0.69–0.94; p=0.006)

Suppressed viral loads reported in 156 of 273 patients in the SMS group and 128 of 265 in the control group (RR for virologic failure 0.84, 95% CI 0.71–0.99; p=0.04)

Lester 2006

Survey

111 patients

-89% nine per cent had access to a phone
-12% had ever called or been called by healthcare worker

- confidentiality barriers: preference to talk with clinic staff in person and issues regarding stigma or confidentiality
- 54% said they would be comfortable receiving HIV-related information by telephone
- logistical issues

Pop-Eleches 2011

Medication adherence reminder

HIV

Kenya

SMS for ART adherence

Randomized controlled trial

Patients initiating ART, 4 intervention groups (70, 72, 73, 74 patients respectively), 139 patients control group

- longer SMS reminders were not more effective than either a short reminder or no reminder.
- weekly reminders improved adherence, whereas daily reminders did not.
- patients losing their mobile and changing numbers

53% of participants receiving SMS reminders achieved adherence of at least 90% during the 48 weeks of the study, compared with 40% of participants in the control group (p<0.03)

Kunutsor 2010
