Förster-type nonradiative energy transfer (NRET) provides us with the ability to transfer excitation energy between proximal nanostructures with high efficiency under certain conditions. Nevertheless, the well-known Förster theory was developed for the case of a single donor (e.g., a molecule, a dye) together with single acceptor. There is no complete understanding for the cases when the donors and the acceptors are assembled in nanostructure arrays, though there are special cases previously studied. Thus, a comprehensive theory that models Förster-type NRET for assembled nanostructure arrays is required. Here, we report a theoretical framework of generalized theory for the Förster-type NRET with mixed dimensionality in arrays. These include combinations of arrayed nanostructures made of nanoparticles (NPs) and nanowires (NWs) assemblies in one-dimension (1D), two-dimension (2D), and three-dimension (3D) completing the framework for the transfer rates in all possible combinations of different confinement geometries and assembly architectures, we obtain a unified picture of NRET in assembled nanostructures arrays. We find that the generic NRET distance dependence is modified by arraying the nanostructures. For an acceptor NP the rate distance dependence changes from $\gamma \propto d^{-6}$ to $\gamma \propto d^{-5}$ when they are arranged in a 1D stack, and to $\gamma \propto d^{-4}$ when in a 2D array, and to $\gamma \propto d^{-3}$ when in a 3D array. Likewise, an acceptor NW changes its distance dependence from $\gamma \propto d^{-5}$ to $\gamma \propto d^{-4}$ when they are arranged in a 1D array and to $\gamma \propto d^{-3}$ when in a 2D array. These finding shows that the numbers of dimensions across which nanostructures are stacked is equally critical as the confinement dimension of the nanostructure in determining the NRET kinetics.

I. INTRODUCTION

Modern nanotechnology allows for the fabrication of superstructures composed of nanoparticles and nanowires as building blocks.\textsuperscript{1-9} Each element of the nanostructure contributes to the overall structure with their distinctive properties resulting from quantum confinement and interactions between them which enhances optical properties for the structure. The Förster-type nonradiative energy transfer (NRET) is an important mechanism for strong coupling between elements (the donor and the acceptor) based on the Coulomb (dipole-dipole) interaction.\textsuperscript{10,11} NRET can be an efficient mechanism to couple optically excited nanostructures.\textsuperscript{12-15} The energy transfer between the elements that results from the Coulombic interaction can be seen by the exciton flow from the donor (D) to the acceptor (A) (D→A).\textsuperscript{16-20} Excitons play an important role in optical devices. They can be used for storage reservoir of light energy. This makes semiconductor nanoparticles and nanowires attractive for solar cell applications,\textsuperscript{21,22} lasers,\textsuperscript{23,24} photodetectors,\textsuperscript{25,26} and LEDs\textsuperscript{27} as well as device interconnects.\textsuperscript{28-31} Thus, understanding NRET in these nanostructures is crucial for high efficiency light generation and harvesting.

In this article, we present the theoretical framework of generalized Förster-type NRET between one-dimensional (1D) or two-dimensional (2D) assemblies of nanostructures made of nanoparticles (NPs) and nanowires (NWs). The change on NRET mechanism with respect to the donor vs the acceptor is investigated, paying particular attention to the functional distance dependence of the transfer rate. In this work, we considered the combinations of X→1D assembly of NPs, X→2D assembly of NPs, X→3D assembly of NPs, X→1D assembly of NWs, and X→2D assembly of NWs where X is a NP, NW, or quantum well (QW) because of their practical applications as stated earlier. Furthermore, we obtained a complete set of analytical
expressions in the long distance approximation for all above-mentioned cases; and then, derived
generic expressions for the dimensionality involved giving a complete picture and unified
understanding of NRET for nanostructure assemblies.

II. THEORETICAL FORMALISM FOR FÖRSTER-TYPE NONRADIATIVE ENERGY
TRANSFER

In this section, we study the energy transfer process from a single nanostructure (NP, NW, or
QW) to assemblies of NPs and NWs. More specifically, we investigate the following cases: (1)
NP → 1D NP assembly (linear chain); (2) NP → 2D NP assembly (NPs layer or plane); (3)
NP → 3D NP assembly; (4) NP → 1D NW assembly (plane); (5) NP → 2D NW assembly; (6)
NW → 1D NP assembly; (7) NW → 2D NP assembly; (8) NW → 3D NP assembly; (9) NW → 1D
NW assembly; (10) NW → 2D NW assembly; (11) QW → 1D NP assembly; (12) QW → 2D NP
assembly; (13) QW → 3D NP assembly; (14) QW → 1D NW assembly; and (15) QW → 2D NW
assembly. For all cases, an analytical expression for the long distance approximation is given. In
addition, at the beginning of this section, the macroscopic approach to the problem of dipole-
dipole energy transfer is outlined.

The Fermi’s Golden rule gives the probability for an exciton to be transferred from a donor to
an acceptor (eq. (1)).

\[
\gamma_{\text{trans}} = \frac{2}{\hbar} \sum_{f} \left| \langle f_{\text{exc}} ; 0_{\text{exc}} | \hat{V}_{\text{int}} | i_{\text{exc}} ; 0_{\text{exc}} \rangle \right|^2 \delta \left( \hbar \omega_{\text{exc}} - \hbar \omega_f \right)
\]  

(1)
where \( |i_{\text{exc}};0_{\text{exc}}\rangle\) is the initial state with an exciton in the donor and zero exciton in the acceptor; 
\( |f_{\text{exc}};0_{\text{exc}}\rangle\) is the final state with an exciton in the acceptor and zero exciton in the donor; \( \hat{V}_{\text{int}} \) is the exciton Coulomb interaction operator; and \( \hbar \omega_{\text{exc}} \) is the energy of the exciton. As described elsewhere,\(^{19,32,33}\) this expression can be simplified into

\[
\gamma_{\text{trans}} = \frac{2}{\hbar} \text{Im} \left[ \int dV \left( \frac{\varepsilon_A(\omega)}{4\pi} \right) E_{\text{in}}(r) \cdot E_{\text{in}}^*(r) \right]
\]  

(2)

where the integration is taken over the acceptor volume, \( \varepsilon_A(\omega) \) is the acceptor’s dielectric function, and \( E_{\text{in}}(r) \) is the effective electric field created by an exciton at the donor side. Here, the electric field is given by \( E(r) = -\nabla \Phi(r) \) and the electric potential \( \Phi(r) \) is

\[
\Phi_\alpha(r) = \left( \frac{ed_{\text{exc}}}{\varepsilon_{\text{eff}}_D} \right) \frac{(r - r_0) \cdot \hat{\alpha}}{|r - r_0|^3}
\]

(3)

where \( ed_{\text{exc}} \) is the exciton dipole moment and \( \varepsilon_{\text{eff}}_D \) is the donor’s effective dielectric constant, which depends on the geometry and the exciton dipole direction, \( \alpha = x, y, z \). Table S1 provides a summary for the donor dielectric constant as calculated for a single donor in ref 34 in the Supporting Information.

At room temperature, the average NRET rate is calculated as

\[
\gamma_{\text{trans}} = \gamma_{x,\text{trans}} + \gamma_{y,\text{trans}} + \gamma_{z,\text{trans}}
\]

(4)

where \( \gamma_{\alpha,\text{trans}} \) is the energy transfer rate for the \( \alpha \)-exciton \( (\alpha = x, y, z) \). In the following subsection, the results obtained in ref 34 are used to derive expression for the assembly cases.
A. NANOPARTICLE, NANOWIRE, OR QUANTUM WELL → 1D NANOPARTICLE ASSEMBLY ENERGY TRANSFER RATES

The NRET rate analytical equations, in the long distance approximation, when the donor is a NP, a NW, or a QW and the acceptor is a 1D NP assembly (linear chain) (Figure 1) are derived. Under the assumption that the donor size is smaller than the separation distance between the D-A pair and using the long distance approximation, the energy transfer rate $\gamma_{a,i}$ from the donor and the $i$-th NP in the 1D NP assembly (chain) is given by

$$\gamma_{a,i} = \frac{2}{\hbar} b_{a} \left( \frac{e d_{\text{exc}}}{\epsilon_{\text{eff}} (\omega)} \right)^{2} R_{\text{NPA}}^{3} \left| \frac{3 \epsilon_{0}}{\epsilon_{\text{NPA}} (\omega) + 2 \epsilon_{0}} \right| \text{Im} \left| \epsilon_{\text{NPA}} (\omega) \right| \frac{1}{(r^{2} + y_{i}^{2})^{3}}$$

(5)

where $b_{a} = \frac{1}{3}, \frac{1}{3}, \frac{4}{3}$ for $\alpha = x, y, z$, respectively; $e d_{\text{exc}}$ is the exciton dipole moment; $\epsilon_{\text{eff}} (\omega)$ is the effective dielectric constant for the exciton in the donor given in Table S1 (see Supporting Information); $\epsilon_{0}$ is the medium dielectric constant; $R_{\text{NPA}}$ and $\epsilon_{\text{NPA}}$ are the acceptor NP radius and dielectric function, respectively; and $r$ is the distance between the donor and linear NP chain (Figure 1). The total transfer from the donor to all acceptor NP in the chain is

$$\gamma_{a} = \sum_{i} \gamma_{a,i} = \frac{2}{\hbar} b_{a} \left( \frac{e d_{\text{exc}}}{\epsilon_{\text{eff}} (\omega)} \right)^{2} R_{\text{NPA}}^{3} \left| \frac{3 \epsilon_{0}}{\epsilon_{\text{NPA}} (\omega) + 2 \epsilon_{0}} \right| \text{Im} \left| \epsilon_{\text{NPA}} (\omega) \right| \sum_{i} \frac{1}{(r^{2} + y_{i}^{2})^{3}}$$

(6)

if the separation between NP is small and a linear density of particle $\lambda_{NP}$ is defined, then eq. (6) can be written as

$$\gamma_{a} = \frac{2}{\hbar} b_{a} \left( \frac{e d_{\text{exc}}}{\epsilon_{\text{eff}} (\omega)} \right)^{2} R_{\text{NPA}}^{3} \left| \frac{3 \epsilon_{0}}{\epsilon_{\text{NPA}} (\omega) + 2 \epsilon_{0}} \right| \text{Im} \left| \epsilon_{\text{NPA}} (\omega) \right| \int_{-\infty}^{\infty} \frac{\lambda_{NP}}{(r^{2} + y^{2})^{3}} \text{d}y$$

(7)

After integration, the expression boils down to
\[
\gamma_{\alpha} = \frac{2}{h} b^2 \left( \frac{e d_{\text{exc}}}{\epsilon_{\text{eff,D}}} \right)^2 \left( \frac{3\pi R_{\text{NP}}^3}{8} \right) \frac{\lambda_{\text{NP}}}{d^5} \left( c_D \right)^5 \frac{3\epsilon_0}{\epsilon_{\text{NP}}(\omega) + 2\epsilon_0} \right|^2 \text{Im} \epsilon_{\text{NP}}(\omega) \right| \tag{8}
\]

where \( d \) is the distance between the donor and linear NP chain and \( c_D \) is a constant, which depends on the donor geometry; \( c_D = 1, \cos(\theta_0) \) for NP and QW, respectively, and \( (1 + \tan^2 \theta_0 \sin^2 \alpha)^{-1/2} \) for a NW. \( \theta_0 \) is the angle between \( r \) and \( d \) as show in Figure 1b,c. \( \alpha \) is the angle between NW axis and the NP array axis (Figure 1b). Note that the energy transfer rate distance dependency changes from \( \gamma \propto d^{-6} \) to \( \gamma \propto d^{-5} \). Furthermore, the NRET rate eq. (8) strongly depends on the angle or angles when the donor is a QW or NW, respectively.
**Figure 1:** Schematic for the energy transfer of (a) NP→1D NP assembly, (b) NW→1D NP assembly, and (c) QW→1D NP assembly. Orange arrows show the energy transfer direction. Yellow circles represent an exciton in the α-direction. $d$ is the separation distance. $\theta_0$ is the azimuthal angle between $d$ and $r$. $\alpha$ is the angle between NW axis and the NP array axis.

**B. NANOPARTICLE, NANOWIRE, OR QUANTUM WELL → 2D NANOPARTICLE ASSEMBLY ENERGY TRANSFER RATES**

We present a simplified expression for NRET rate in the long distance approximation when the donor is a NP, a NW, or a QW and the acceptor is a 2D NP assembly (plane) (Figure 2). Under the same assumptions as the previous case, the energy transfer from a donor NP to the $i,j$-th acceptor NP in a 2D assembly can be written as

$$\gamma_{a,i,j} = \frac{2}{\hbar} b_a \left( \frac{e d_{\text{exc}}}{\epsilon_{\text{eff},a}} \right)^2 R_{\text{NPA}}^3 \left| \frac{3\epsilon_0}{\epsilon_{\text{NPA}}(\omega) + 2\epsilon_0} \right|^2 \text{Im} \left| \epsilon_{\text{NPA}}(\omega) \right| \frac{1}{\left( d^2 + \rho_{i,j}^2 \right)^3}$$  \hspace{1cm} (9)

Thus, the total transfer rate is given by

$$\gamma_a = \sum_{i,j} \gamma_{a,i,j} = \frac{2}{\hbar} b_a \left( \frac{e d_{\text{exc}}}{\epsilon_{\text{eff},a}} \right)^2 R_{\text{NPA}}^3 \left| \frac{3\epsilon_0}{\epsilon_{\text{NPA}}(\omega) + 2\epsilon_0} \right|^2 \text{Im} \left| \epsilon_{\text{NPA}}(\omega) \right| \sum_{i,j} \frac{1}{\left( d^2 + \rho_{i,j}^2 \right)^3}$$ \hspace{1cm} (10)

Assuming the separation between acceptor NP is small and a surface density of particle $\sigma_{\text{NP}}$, eq. (10) reduces to

$$\gamma_a = \frac{2}{\hbar} b_a \left( \frac{e d_{\text{exc}}}{\epsilon_{\text{eff},a}} \right)^2 R_{\text{NPA}}^3 \left| \frac{3\epsilon_0}{\epsilon_{\text{NPA}}(\omega) + 2\epsilon_0} \right|^2 \text{Im} \left| \epsilon_{\text{NPA}}(\omega) \right| \int_0^\infty \int_0^{2\pi} \frac{2\pi\sigma_{\text{NP}}}{\left( d^2 + \rho^2 \right)^3} \rho d\rho$$ \hspace{1cm} (11)

The final equation for the transfer rate is
\[ \gamma_a = \frac{2}{h} \left( \frac{e d_{\text{exc}}}{\varepsilon_{\text{eff}}(0)} \right) \left( \frac{\pi R_{\text{PA}}^3}{2} \right) \sigma_{\text{NP}} \left| \frac{3\varepsilon_0}{\varepsilon_{\text{PA}}(\omega)} + 2\varepsilon_0 \right|^2 \right] \text{Im} \left| \varepsilon_{\text{NP}}(\omega) \right| \]

(12)

For this case, the energy transfer rate distance dependency changes from \( \gamma \propto d^{-6} \) to \( \gamma \propto d^{-4} \).

This result is consistent with a previous study in refs 35-37.

**Figure 2**: Schematic for the energy transfer of (a) NP→2D NP assembly, (b) NW→2D NP assembly, and (c) QW→2D NP assembly. Orange arrows denote the energy transfer direction. Yellow circles represent an exciton in the \( \alpha \)-direction. \( d \) is the separation distance. \( \theta_0 \) is the azimuthal angle between \( d \) and \( r \).
C. NANOPARTICLE, NANOWIRE, OR QUANTUM WELL \(\rightarrow\) 3D NANOPARTICLE ASSEMBLY ENERGY TRANSFER RATES

The NRET rate expression in the long distance approximation when the donor is a NP, a NW, or a QW and the acceptor is a 3D NP assembly is obtained (Figure 3). In the same spirit to the previous cases, the energy transfer from a donor NP to the \(i,j,k\)-th acceptor NP in a 3D assembly is

\[
\gamma_{a,i,j,k} = \frac{2}{\hbar} b_a \left( \frac{e d_{\text{exc}}}{\epsilon_{\text{eff},0}} \right)^2 R_{\text{NPA}}^3 \left| \frac{3\epsilon_0}{\epsilon_{\text{NPA}}(\omega) + 2\epsilon_0} \right|^2 \text{Im}\left| \epsilon_{\text{NPA}}(\omega) \right| \frac{1}{(x_{ijk}^2 + y_{ijk}^2 + (z_{ijk} + d)^2)^{3/2}}
\]

(13)

Thus, the total transfer rate is given by

\[
\gamma_a = \sum_{i,j,k} \gamma_{a,i,j,k} = \frac{2}{\hbar} b_a \left( \frac{e d_{\text{exc}}}{\epsilon_{\text{eff},0}} \right)^2 R_{\text{NPA}}^3 \left| \frac{3\epsilon_0}{\epsilon_{\text{NPA}}(\omega) + 2\epsilon_0} \right|^2 \text{Im}\left| \epsilon_{\text{NPA}}(\omega) \right| \sum_{i,j,k} \frac{1}{(x_{ijk}^2 + y_{ijk}^2 + (z_{ijk} + d)^2)^{3/2}}
\]

(14)

Assuming the separation between acceptor NP is small and a volume density of particle \(\rho_{\text{NP}}\), eq. (10) reduces to

\[
\gamma_a = \frac{2}{\hbar} b_a \left( \frac{e d_{\text{exc}}}{\epsilon_{\text{eff},0}} \right)^2 R_{\text{NPA}}^3 \left| \frac{3\epsilon_0}{\epsilon_{\text{NPA}}(\omega) + 2\epsilon_0} \right|^2 \text{Im}\left| \epsilon_{\text{NPA}}(\omega) \right| \frac{\rho_{\text{NP}}}{\int_{0}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{\rho_{\text{NP}}}{(x^2 + y^2 + (z + d)^2)^{3/2}}} dx dy dz
\]

(15)

The final equation for the transfer rate is

\[
\gamma_a = \frac{2}{\hbar} b_a \left( \frac{e d_{\text{exc}}}{\epsilon_{\text{eff},0}} \right)^2 \left( \frac{\pi R_{\text{NPA}}^3}{6} \right) \frac{\rho_{\text{NP}}}{d^3} \left| \frac{3\epsilon_0}{\epsilon_{\text{NPA}}(\omega) + 2\epsilon_0} \right|^2 \text{Im}\left| \epsilon_{\text{NPA}}(\omega) \right|
\]

(16)

For this case, the NRET rate distance dependency changes from \(\gamma \propto d^{-6}\) to \(\gamma \propto d^{-3}\) similar to the bulk case.
Figure 3: Schematic for the energy transfer of (a) NP→3D NP assembly, (b) NW→3D NP assembly, and (c) QW→3D NP assembly. Orange arrows denote the energy transfer direction. Yellow circles represent an exciton in the $\alpha$-direction. $d$ is the separation distance. $\theta_0$ is the azimuthal angle between $d$ and $r$.

D. NANOPARTICLE, NANOWIRE, OR QUANTUM WELL → 1D NANOWIRE ASSEMBLY ENERGY TRANSFER RATES
We derive simplified expressions for NRET rate in the long distance approximation when the donor is a NP, a NW, or a QW and the acceptor is a 1D NW assembly (Figure 4). In the same way as in the cases above, we consider the energy transfer rate between the donor and the 1D assembly of NWs. In this case, the transfer rate to the $i$-th NW is

$$\gamma_{\alpha,i} = \frac{2}{h} \left( \frac{e d_{\text{exc}}}{\varepsilon_{\text{eff},d}} \right)^2 \left( \frac{3\pi}{32} \right) R_{\text{NWA}}^2 \left( a_\alpha + b_\alpha \left| \frac{2 \varepsilon_0}{\varepsilon_{\text{NWA}}^{\alpha}(\omega) + \varepsilon_0} \right|^2 \right) \text{Im} \left| \varepsilon_{\text{NWA}}^{\alpha}(\omega) \right| \frac{1}{\left( d^2 + y_i^2 \right)^{\frac{3}{2}}}$$  \hspace{1cm} (17)

where $a_\alpha = 0, \frac{9}{16}, \frac{15}{16}$ and $b_\alpha = 1, \frac{12}{16}, \frac{41}{16}$ for $\alpha = x, y, z$, respectively; $\varepsilon_{\text{eff},d}$ is the effective dielectric constant for the exciton in the donor NP given in Table S1, Supporting Information; $R_{\text{NWA}}$ is the acceptor NW radius; and $d$ is the distance between the donor and NW assembly (Figure 4). The total transfer from the donor to all acceptor NWs in the chain is

$$\gamma_\alpha = \sum_i \gamma_{\alpha,i} = \frac{2}{h} \left( \frac{e d_{\text{exc}}}{\varepsilon_{\text{eff},d}} \right)^2 \left( \frac{3\pi}{32} \right) R_{\text{NWA}}^2 \left( a_\alpha + b_\alpha \left| \frac{2 \varepsilon_0}{\varepsilon_{\text{NWA}}^{\alpha}(\omega) + \varepsilon_0} \right|^2 \right) \text{Im} \left| \varepsilon_{\text{NWA}}^{\alpha}(\omega) \right| \sum_i \frac{1}{\left( d^2 + y_i^2 \right)^{\frac{3}{2}}}$$  \hspace{1cm} (18)

Under the assumption that the NWs are close to each other with a linear density $\lambda_{\text{NW}}$,

$$\gamma_\alpha = \frac{2}{h} \left( \frac{e d_{\text{exc}}}{\varepsilon_{\text{eff},d}} \right)^2 \left( \frac{3\pi}{32} \right) R_{\text{NWA}}^2 \left( a_\alpha + b_\alpha \left| \frac{2 \varepsilon_0}{\varepsilon_{\text{NWA}}^{\alpha}(\omega) + \varepsilon_0} \right|^2 \right) \text{Im} \left| \varepsilon_{\text{NWA}}^{\alpha}(\omega) \right| \int_{-\infty}^{\infty} \frac{\lambda_{\text{NW}}}{\left( d^2 + y^2 \right)^{\frac{3}{2}}} dy$$  \hspace{1cm} (19)

The final result is

$$\gamma_\alpha = \frac{2}{h} \left( \frac{e d_{\text{exc}}}{\varepsilon_{\text{eff},d}} \right)^2 \left( \frac{\pi R_{\text{NWA}}^2}{8} \right) \left( \frac{\lambda_{\text{NW}}}{d^4} \right) \left( a_\alpha + b_\alpha \left| \frac{2 \varepsilon_0}{\varepsilon_{\text{NWA}}^{\alpha}(\omega) + \varepsilon_0} \right|^2 \right) \text{Im} \left| \varepsilon_{\text{NWA}}^{\alpha}(\omega) \right|$$  \hspace{1cm} (20)

It is observed that when the NWs are assembled with high density, the transfer rate distance dependency changes from $d^{-5}$ to $d^{-4}$. A similar result can be found in ref 38 for the case of NW $\rightarrow$ 1D NW array.
Figure 4: Schematic for the energy transfer of (a) NP→1D NW assembly, (b) NW→1D NW assembly, and (c) QW→1D NW assembly. Orange arrows show the energy transfer direction. Yellow circles represent an exciton in the α-direction. $d$ is the separation distance. $\theta_\alpha$ is the azimuthal angle between $d$ and $r$.

E. NANOPARTICLE, NANOWIRE, OR QUANTUM WELL → 2D NANOWIRE ASSEMBLY ENERGY TRANSFER RATES

The NRET rate expression in the long distance approximation when the donor is a NP, a NW, or a QW and the acceptor is a 2D NW assembly is derived (Figure 5). Similarly, we consider the
energy transfer rate between the donor and the 2D assembly of NWs. In this case, the transfer rate to the \(i,j\)-th NW is

\[
\gamma_{a,i,j} = \frac{2}{\hbar} \left( \frac{ed_{\text{exc}}}{\varepsilon_{\text{eff},0}} \right)^2 \left( \frac{3\pi}{32} \right) R_{NW}^2 \left( a + b \left| \frac{2\varepsilon_0}{\varepsilon_{NW}(\omega) + \varepsilon_0} \right|^2 \right) \text{Im} \left| \varepsilon_{NW}(\omega) \right| \frac{1}{\left( y_{i,j}^2 + (d + z_{i,j})^2 \right)^{\frac{3}{2}}}
\]  

(21)

The total transfer from the donor to all acceptor NWs in the array is

\[
\gamma_a = \sum_{i,j} \gamma_{a,i,j} = \frac{2}{\hbar} \left( \frac{ed_{\text{exc}}}{\varepsilon_{\text{eff},0}} \right)^2 \left( \frac{3\pi}{32} \right) R_{NW}^2 \left( a + b \left| \frac{2\varepsilon_0}{\varepsilon_{NW}(\omega) + \varepsilon_0} \right|^2 \right) \text{Im} \left| \varepsilon_{NW}(\omega) \right| \sum_{i,j} \frac{1}{\left( y_{i,j}^2 + (d + z_{i,j})^2 \right)^{\frac{3}{2}}}
\]  

(22)

Under the assumption that the NWs are close to each other with a surface density \(\sigma_{NW}\),

\[
\gamma_a = \frac{2}{\hbar} \left( \frac{ed_{\text{exc}}}{\varepsilon_{\text{eff},0}} \right)^2 \left( \frac{3\pi}{32} \right) R_{NW}^2 \left( a + b \left| \frac{2\varepsilon_0}{\varepsilon_{NW}(\omega) + \varepsilon_0} \right|^2 \right) \text{Im} \left| \varepsilon_{NW}(\omega) \right| \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{\sigma_{NW}}{\left( y^2 + (d + z)^2 \right)^{\frac{3}{2}}} \, dy \, dz
\]  

(23)

The final result is

\[
\gamma_a = \frac{2}{\hbar} \left( \frac{ed_{\text{exc}}}{\varepsilon_{\text{eff},0}} \right)^2 \left( \frac{\pi R_{NW}^2}{24} \right) \left( \frac{\sigma_{NW}}{d^3} \right) \left( a + b \left| \frac{2\varepsilon_0}{\varepsilon_{NW}(\omega) + \varepsilon_0} \right|^2 \right) \text{Im} \left| \varepsilon_{NW}(\omega) \right|
\]  

(24)

It worth mentioning that when the NWs are assembled with high density 2D array, the transfer rate distance dependency changes from \(d^{-5}\) to \(d^{-3}\). This result resembles the bulk case.
**Figure 5:** Schematic for the energy transfer of (a) NP→2D NW assembly, (b) NW→2D NW assembly, and (c) QW→2D NW assembly. Orange arrows show the energy transfer direction. Yellow circles represent an exciton in the α-direction. $d$ is the separation distance. $\theta_0$ is the azimuthal angle between $d$ and $r$.

Table 1 summarizes the energy transfer rates in the long distance and dipole approximation for all combinations and all possible arrayed architectures presented in this work. Table 1 also illustrates the NRET rate generic distance dependence with equivalent cases in term of $d$. 

dependence. In all cases, the acceptor geometry and array architecture gives the NRET rate distance dependency, for example, when the acceptor is (1) an 1D NP assembly, $\gamma \propto d^{-5}$ (eq. (8)); (2) an 2D NP assembly, $\gamma \propto d^{-4}$ (eq. (12)); and (3) a 1D NW assembly, $\gamma \propto d^{-4}$ (eq. (20)). This suggests the NRET distance dependency is independent of the donor dimensionality (NP, NW, QW); however, as shown in the above equations, the geometry of the donor only affects the effective dielectric constant. These new results corroborate with the results obtained in ref 34. Hence, we infer that the functional distance dependency of the NRET rate is ruled by the degree of confinement of the acceptor nanostructure and its array dimensions; whereas the confinement of the donor modifies the effective dielectric constant. Figure 6 illustrates the transfer rate, in the long distance approximation, for two particular cases. The linear density of NP and NW was taken as $10^8$ NPs/m and $7 \times 10^7$ NWs/m, respectively. Figure 6a shows the transfer rates from a NP, a NW, or a QW to a 1D NP array. In this, the transfer rates are in the range of $ns^{-1}$, which is typical for CdTe NP. However, the difference is that the transfer rate follows $d^{-5}$ distance dependence compared to $d^{-6}$ for a single NP. Similarly, Figure 6b shows the transfer rates from a NP, a NW, or a QW to a 1D NW array. Here, the transfer rate follows $d^{-4}$ distance dependence compared to $d^{-5}$ for a single NW. It is worth mentioning that the expression derived in this work holds for the case of metal nanostructures as the acceptor. However, in this case, the transfer rate will be larger compared to the semiconductor case because of the high absorption of the metallic structures, especially in the regime of plasmonic resonance, $\lambda_{\text{exciton}} \approx \lambda_{\text{plasmon}}$. This behavior is explicit on the imaginary part of the dielectric constants in all our expressions.
Figure 6: Energy transfer rate, in the long distance approximation, for a CdTe (a) 1D NP and (b) 1D NW array. Red, green, and blue lines correspond to a NP, a NW, and a QW as a donor, respectively. The linear density of NP and NW was taken as $10^8$ NPs/m and $7 \times 10^7$ NWs/m, respectively.

To finish this work, we briefly list the limitations of our approach. (a) Equation (3), which computes the induced electric fields inside a nanostructure, applies when simplified wave functions for the exciton is used, i.e., we neglect the mixing between heavy- and light-hole states. However, in general, the heavy- and light-holes are mixed in the valence band giving to the exciton wave function a complex form. (b) Our model is based on the local dielectric constant and becomes less effective for very small nanostructures because of the additional trap surface states for exciton created at the surface. (c) The expressions obtained here are based on the long distance approximation, i.e., when the separation distance between the donor and the acceptor is much larger than the donor and the acceptor size. In the case where the long distance approximation failed, the transfer rate should follow the dipole-to-surface transfer rate.$^{39}$

$d$: distance between D and A, $\equiv$: equivalent.

Generic distance dependency for the NRET rates, with equivalent cases of arrayed nanostructures in term of $d$ dependence.

### III. CONCLUSION

In this work, we present a complete picture and unified understanding of the nonradiative energy transfer in assembled nanostructures arrays. The analytical expressions for the energy transfer rate in the long distance approximation were obtained. Our findings show that while the
acceptor quantum confinement dimension sets the generic NRET distance dependence and the
donor geometry dimension modifies the dielectric function, this generic distance dependence can
be remodified by arraying (stacking) the nanostructures. For example, the rate distance
dependence for an acceptor NP changes from $\gamma \propto d^{-6}$ to $\gamma \propto d^{-5}$ when the NP is arranged in a
1D stack, which is equivalent to the single NW case. Similarly, the NRET distance dependence
for an acceptor NW changes from $\gamma \propto d^{-5}$ to $\gamma \propto d^{-3}$ when they are arranged in a 2D array,
equivalent to the bulk case. Therefore, the functional distance dependency of the NRET rate is
determined by the quantum confinement as well as array stacking dimensionality of the acceptor.
The NRET results obtained in this work can be used to design and optimize new solid-state
devices for high efficiency light generation and harvesting. The formalism developed here is
convenient to estimate the NRET rates in experimental studies involving assembled
nanostructure arrays.
