We study the existence and uniqueness of positive solutions for a class of singular $m$-point boundary value problems of second order differential equations on a measure chain. A sharper sufficient condition for the existence and uniqueness of $C^1_{rd}[0, T]$ positive solutions as well as $C^1_{rd}[0, T]$ positive solutions is obtained by the technique of lower and upper solutions and the maximal principle theorem.

1. Introduction

In this paper, we present the existence of positive solutions for the following second order singular $m$-point boundary value problem on a measure chain:

\[ x^{\Delta\Delta}(t) + a(t)f(t, x(t)) = 0, \quad 0 < t < T, \quad (1) \]
\[ x(T) = 0, \quad x(0) = \sum_{i=1}^{m-2} \alpha_i x(\eta_i), \quad (2) \]

where $0 < \alpha_i < T$, $i = 1, \ldots, m - 2$, $0 < \eta_1 < \eta_2 < \cdots < \eta_{m-2} < T$ are constants and $0 < \Sigma_{i=1}^{m-2} \alpha_i < T$, $m \geq 3$. We assume that $0 < T < +\infty$ belong to $\mathbb{T}$. We use $(0, T)$ to denote $(0, T) \cap \mathbb{T}$, and similar notations are used for other intervals. The function $a : (0, T) \rightarrow [0, +\infty)$ is rd-continuous, $f : (0, T) \times (0, +\infty) \rightarrow [0, +\infty)$ is continuous, and $f(t, x)$ may be singular at $t = 0$ and $t = T$, $x = 0$. Observe that when $\mathbb{T} = \mathbb{R}$ or $\mathbb{T} = \mathbb{Z}$, the problem (1)-(2) reduces to boundary value problems of ordinary differential equations or difference equations.

The existence of positive solutions for boundary value problem on a measure chain has been paid more attentions by many researchers. Related problems on measure chains can be found in [1-9].

Recently, by making use of the Krasnosel’skii fixed point theorem, Goodrich [1] studied the existence of at least one positive solution for the following boundary value problem:

\[ u^{\Delta\Delta}(t) + \lambda f(t, u(t)) = 0, \quad t \in (a, \sigma^2(b)), \]
\[ u(a) = \phi(u), \quad \alpha u^{\sigma^2}(b) = 0, \quad (3) \]

where the nonlocal boundary condition $\phi : C_{rd}([a, \sigma^2(b)]_{\mathbb{T}}, \mathbb{R}) \rightarrow [0, +\infty)$ is continuous.

Sun and Li [5] gave the existence results of the following three-point boundary value problem on time scale $\mathbb{T}$:

\[ x^{\Delta\Delta}(t) + a(t)f(t, x(t)) = 0, \quad t \in (0, T) \subset \mathbb{T}, \]
\[ \beta x(0) - \gamma x^{\sigma}(0) = 0, \quad \alpha x(\eta) = x(T), \quad (4) \]

where $\beta, \gamma \geq 0$, $\beta + \gamma > 0$, $\eta \in (0, \rho(t))$, $0 < \alpha < T/\eta$, and $d = \beta(T - \alpha \eta) + \gamma(1 - \alpha) > 0$.

By applying functional-type cone expansion-compression fixed point theorem, P. Wang and Y. Wang [6] established the existence of positive solutions of the following nonlinear
boundary value problem given by the dynamic equation on time scales:
\[
\begin{align*}
x^\Delta (t) + a(t) f(t, x(t)) &= 0, \quad t \in (0, T) \subset \mathbb{T}, \\
\beta x(0) - \gamma x^\Delta (0) &= 0, \\
\alpha x(T) - \sum_{i=1}^{m-2} a_i x(\xi_i) &= b, \quad m \geq 3.
\end{align*}
\] (5)

By employing the Krasnosel’skii fixed point theorem, Hao et al. [2] discussed the existence of positive solutions of the following boundary value problem on a time scale:
\[
\begin{align*}
u^\Delta (t) + m(t) f(t, \nu(t)) &= 0, \quad t \in (a, b), \\
\alpha \nu(a) - \beta \nu^\Delta (a) &= 0, \\
\gamma \nu(\sigma(b)) + \delta \nu^\Delta (\sigma(b)) &= 0.
\end{align*}
\] (6)

Inspired and motivated greatly by the work of [1, 2, 5–9], we establish the existence and uniqueness of positive solution for singular m-point boundary value problem (1)-(2). By constructing lower and upper solutions and using the maximal theorem, we not only obtain a sharper sufficient condition for the existence of positive solution, but also prove a sufficient condition for the existence of positive solution if \(x^\Delta (0+)\) and \(x^\Delta (T-)\) exist, and \(x(t) > 0, t \in [0, T]\).

We state some basic notions connected to time scales, which can be found in [9].

Definition 1. Let \(\mathbb{T}\) be a time scale. For \(t \in \mathbb{T}\), the forward jump operator \(\sigma : \mathbb{T} \to \mathbb{T}\) is defined by
\[
\sigma(t) := \inf \{s \in \mathbb{T} : s > t\},
\] (7) and one defines the backward jump operator \(\rho : \mathbb{T} \to \mathbb{T}\) by
\[
\rho(t) := \sup \{s \in \mathbb{T} : s < t\}.
\] (8)

Definition 2. One says that \(t\) is right-scattered if \(\sigma(t) > t\), and one says that \(t\) is left-scattered if \(\rho(t) < t\). Points are said to be isolated if they are both right-scattered and left-scattered.

Definition 3. One says that \(t\) is right-dense if \(t < \sup \mathbb{T}\) and \(\sigma(t) = t\), and one says that \(t\) is left-dense if \(t > \inf \mathbb{T}\) and \(\rho(t) = t\). Points are said to be dense if they are both right-dense and left-dense. One defines the graininess function \(\mu : \mathbb{T} \to [0, +\infty)\) by
\[
\mu(t) = \sigma(t) - t.
\] (9)

For convenience, one lists the following conditions which will be referred to later:

(H_2) \(a : (0, T) \to [0, +\infty)\) is rd-continuous, and there exists \(t_0 \in [\eta_{m-2}, T]\) such that \(a(t_0) > 0\);

(H_3) \(f : (0, T) \times (0, +\infty) \to [0, +\infty)\) is continuous, and \(f(t, x)\) is nonincreasing with respect to \(x\), for all \(t \in (0, T), a(t) f(t, \cdot) \neq 0\), and
\[
0 < \int_0^T a(t) f(t, \lambda t(T - t)) dt < +\infty, \text{for all } \lambda > 0.
\]

2. Preliminaries and Lemmas

Definition 4. A function \(x(t) \in C_{rd}[0, T] \cap C^2_{rd}(0, T]\) is said to be a \(C_{rd}[0, T]\) positive solution of the problem (1)-(2) if \(x(t)\) satisfies the problem (1)-(2) and \(x(t) > 0, t \in (0, T);\) a \(C_{rd}[0, T]\) positive solution \(x(t)\) of the problem (1)-(2) is said to be a \(C^1_{rd}[0, T]\) positive solution if \(x^\Delta (0+)\) and \(x^\Delta (T-)\) exist, and \(x(t) > 0, t \in [0, T]\).

Definition 5. One says that a function \(\varphi(t) \in C^2_{rd}(0, T]\) is a lower solution of the problem (1)-(2) on \([0, T]\), if \(\varphi(t) \in C_{rd}[0, T] \cap C^2_{rd}[0, T]\) and satisfies
\[
\varphi^\Delta (t) + a(t) f(t, \varphi(t)) \geq 0, \quad t \in (0, T),
\] (10)\[
\varphi(T) \geq 0, \quad \varphi(0) - \sum_{i=1}^{m-2} \alpha_i \varphi(\eta_i) \geq 0.
\] (11)

Similarly, \(\psi(t) \in C^2_{rd}(0, T]\) is said to be an upper solution of the problem (1)-(2) on \([0, T]\), if \(\psi(t) \in C_{rd}[0, T] \cap C^2_{rd}[0, T]\) and satisfies
\[
\psi^\Delta (t) + a(t) f(t, \psi(t)) \leq 0, \quad t \in (0, T),
\] (12)\[
\psi(T) \leq 0, \quad \psi(0) - \sum_{i=1}^{m-2} \alpha_i \psi(\eta_i) \leq 0.
\] (13)

One says \((\varphi(t), \psi(t))\) is a couple of lower and upper solutions of the problem (1)-(2), if there exist a lower solution \(\varphi(t)\) and an upper solution \(\psi(t)\) of the problem (1)-(2) such that
\[
\varphi(t) \leq \psi(t), \quad t \in [0, T].
\] (14)

Lemma 6 (maximal principle). Suppose that \((H_4)\) is satisfied. In addition, assume that \(0 < \eta_1 < \eta_2 < \cdots < \eta_{m-2} < \delta_n < T, \quad n = 1, 2, \ldots, L,\) Let
\[
Q_n = \left\{ x(t) \in C_{rd}[0, \delta_n] \cap C^2_{rd}(0, \delta_n) : x(\delta_n) \geq 0, x(0) - \sum_{i=1}^{m-2} \alpha_i x(\eta_i) \geq 0 \right\},
\] (15) For \(x \in Q_n\) such that \(-x^\Delta(t) \geq 0\) and for \(t \in (0, T)\), then
\[
x(t) \geq 0 \text{ for } t \in [0, \delta_n].
\] (16)
\textbf{Abstract and Applied Analysis}

\textbf{Proof.} For all \( x \in Q_n \), let
\begin{align}
-x^{\Delta\Delta}(t) &= g(t), \quad t \in (0, \delta_n); \quad (14) \\
x(0) - \sum_{i=1}^{m-2} \alpha_i x(\eta_i) &= r_1, \quad x(\delta_n) = r_2, \quad (15)
\end{align}
then \( r_1 \geq 0, r_2 \geq 0 \), and \( g(t) \geq 0, t \in (0, \delta_n) \).

Integrating (14) from 0 to \( t \), we obtain
\begin{equation}
-x^{\Delta}(t) + x^{\Delta}(0) = \int_0^t g(s) \Delta s. \tag{16}
\end{equation}

Again integrating (16) from 0 to \( t \) and exchanging integral sequence, we get
\begin{align}
x(t) &= \frac{1}{A_0} \left( \left( T - \sum_{i=1}^{m-2} \alpha_i \right) t + \sum_{i=1}^{m-2} \alpha_i \eta_i G_n(\eta_i, s) g(s) \Delta s \right) \\
&\quad + \sum_{i=1}^{m-2} \alpha_i \int_0^{T-\delta_n} G_n(\eta_i, s) g(s) \Delta s, \quad t \in (0, \delta_n), \tag{18}
\end{align}
where \( A_0 = \delta_n(T - \sum_{i=1}^{m-2} \alpha_i) + \sum_{i=1}^{m-2} \alpha_i \eta_i > 0 \) and
\begin{equation}
G_n(t, s) = \frac{1}{\delta_n} \begin{cases} 
\eta_i(T - s), & 0 \leq \eta_i < s < \delta_n < T, \\
t(\delta_n - s), & 0 \leq t < s < \delta_n < T.
\end{cases} \tag{19}
\end{equation}

Consequently, from (18) and the definition of \( G_n(t, s) \), we see that \( x(t) \geq 0, t \in [0, \delta_n] \). \qed

Let
\begin{equation}
E = \{ x : [0, T] \rightarrow \mathbb{R} | x(t) \text{ is a nonnegative continuous function} \}
\end{equation}
function, \( x^{\Delta}(t) \) is continuous on \([0, T]\), and \( x^{\Delta\Delta}(t) \) is right-dense continuous on \([0, T] \). \tag{20}

We will use the Banach space \((E, \| \cdot \|)\) equipped with the norm \( \| x \| = \max_{t \in [0, T]} | x(t) |\). Let
\begin{equation}
P = \{ x \in E : \text{there exists a real number} \ m_x, \text{ such that} \ x(t) \geq m_x k(t), \ t \in [0, T] \}, \tag{21}
\end{equation}
where \( k(t) = G(t, t) \). Then \( P \) is a positive cone of \( E \). Define the nonlinear operator \( B \) as follows:
\begin{align}
Bx(t) &= \int_0^T G(t, s) a(s) f(s, x(s)) \Delta s \\
&\quad + A(T - t) \int_0^T G(\eta_i, s) a(s) f(s, x(s)) \Delta s, \tag{22}
\end{align}
which for notational simplicity will be written as
\begin{align}
Bx(t) &= \int_0^T G(t, s) a(s) f(s, x(s)) \Delta s \\
&\quad + A(T - t) \int_0^T G(\eta_i, s) a(s) f(s, x(s)) \Delta s, \tag{23}
\end{align}
where \( \eta_i \in (0, T) \) with \( 0 < \eta_1 < \cdots < \eta_{m-2} < T \) and
\begin{align}
A &= \sum_{i=1}^{m-2} \alpha_i \left( T - \sum_{i=1}^{m-2} \alpha_i \right) + \sum_{i=1}^{m-2} \alpha_i \eta_i, \\
G(t, s) &= \frac{1}{T} \begin{cases} 
t(t - s), & 0 \leq t \leq s \leq T, \\
s(t - \eta_i), & 0 \leq s \leq \eta_i \leq T.
\end{cases} \tag{24}
\end{align}

It is easy to see that
\begin{equation}
k(t) = G(t, t) = \frac{1}{T} T(t - T) - \left( \frac{T}{4} t \right) \leq \frac{T}{4}, \quad t \in [0, T], \tag{25}
\end{equation}

It is clear that the existence of a positive solution of (1)-(2) is equivalent to the existence of a nontrivial fixed point of \( B \) in \( P \).

\textbf{Lemma 7.} Suppose that (H1)-(H3) hold. Then \( BP \subset P \), and \( B \) is a decreasing operator.

\textbf{Proof.} It is obvious that \( k(t) \in P \), so \( P \) is not empty: \( P \neq \emptyset \). For all \( x(t) \in P \), by the definition of \( P \), there exists a real number \( m_x \), such that \( x(t) \geq m_x k(t), t \in [0, T] \). From (H3), we know that
\begin{align}
\int_0^T k(s) a(s) f(s, x(s)) \Delta s \\
\leq \int_0^T k(s) a(s) f(s, m_x k(s)) \Delta s < +\infty.
\end{align}
From the definition of $G(t,s)$ and (23), we find

$$Bx(t) = \int_0^T G(t,s) a(s) f(s,x(s)) \Delta s$$

$$+ A(T-t) \int_0^T G(\eta_i, s) a(s) f(s,x(s)) \Delta s$$

$$\leq \int_0^T k(s) a(s) f(s,x(s)) \Delta s$$

$$+ A(T-t) \int_0^T k(s) a(s) f(s,x(s)) \Delta s$$

$$\leq \frac{T^2-t}{T} \sum_{i=1}^{m-2} \alpha_i + \sum_{i=1}^{m-2} \alpha_i \eta_i$$

$$\times \int_0^T k(s) a(s) f(s,x(s)) \Delta s$$

$$\leq \frac{A(T^2 + \sum_{i=1}^{m-2} \alpha_i \eta_i)}{\sum_{i=1}^{m-2} \alpha_i}$$

$$\times \int_0^T k(s) a(s) f(s,x(s)) \Delta s < +\infty.$$  

(27)

Let $w = \max_{t \in [0,T]} x(t)$. From (H2), we see $\int_0^T k(s)a(s)f(s,w)\Delta s > 0$. Since $f(t,x)$ is continuous on $(0,T) \times (0,\infty)$, thus

$$\int_0^T k(s) a(s) f(s,x(s)) \Delta s$$

$$\geq \int_0^T k(s) a(s) f(s,w) \Delta s > 0.$$  

(28)

On the other hand, for all $x \in P$, by making use of (25), we obtain

$$Bx(t) = \int_0^T G(t,s) a(s) f(s,x(s)) \Delta s$$

$$+ A(T-t) \int_0^T G(\eta_i,s) a(s) f(s,x(s)) \Delta s$$

$$\geq \frac{1}{T} k(t) \int_0^T k(s) a(s) f(s,x(s)) \Delta s$$

$$+ \frac{1}{T} A(T-t) k(\eta_i) \int_0^T k(s) a(s) f(s,x(s)) \Delta s$$

$$\geq \frac{1}{T} \left( 1 + \frac{\sum_{i=1}^{m-2} \alpha_i \eta_i (T-\eta_i)}{T \left( T - \sum_{i=1}^{m-2} \alpha_i \right) + \sum_{i=1}^{m-2} \alpha_i \eta_i} \right)$$

$$\times \int_0^T k(s) a(s) f(s,x(s)) \Delta s \cdot k(t) = m_{Bx} k(t),$$

$$\forall t \in [0,T],$$

(29)

where

$$m_{Bx} = \frac{1}{T} \left( 1 + \frac{\sum_{i=1}^{m-2} \alpha_i \eta_i (T-\eta_i)}{T \left( T - \sum_{i=1}^{m-2} \alpha_i \right) + \sum_{i=1}^{m-2} \alpha_i \eta_i} \right)$$

$$\times \int_0^T k(s) a(s) f(s,x(s)) \Delta s.$$  

Therefore $Bx$ is well defined on $P$, and $Bx \in P$ for all $x \in P$. So $BP \subset P$.

For all $x_1, x_2 \in P$ with $x_1 < x_2$, from (H2), we see that

$$(Bx_1)(t) = \int_0^T G(t,s) a(s) f(s,x_1(s)) \Delta s$$

$$+ A(T-t) \int_0^T G(\eta_i,s) a(s) f(s,x_1(s)) \Delta s$$

$$\geq \int_0^T G(t,s) a(s) f(s,x_2(s)) \Delta s$$

$$+ A(T-t) \int_0^T G(\eta_i,s) a(s) f(s,x_2(s)) \Delta s$$

$$= (Bx_2)(t).$$  

(30)

Therefore, $(Bx_1)(t) \geq (Bx_2)(t)$ and hence $B$ is a decreasing operator.

Lemma 8. Suppose that (H1)–(H3) hold. Then for any $x \in P$, the problem (1)-(2) has an upper solution $\bar{x}$ and a lower solution $\underline{x}$, and $(\underline{x}(t),\bar{x}(t))$ is a couple of lower and upper solution of the problem (1)-(2).

Proof. For all $x \in P$, we know that

$$(Bx)(t) = \int_0^T G(t,s) a(s) f(s,x(s)) \Delta s$$

$$+ A(T-t) \int_0^T G(\eta_i,s) a(s) f(s,x(s)) \Delta s$$

$$= \frac{1}{T} \int_0^T sa(s) f(s,x(s)) \Delta s$$

$$+ \frac{1}{T} \int_0^T (T-s) a(s) f(s,x(s)) \Delta s$$

$$+ A(T-t) \int_0^T G(\eta_i,s) a(s) f(s,x(s)) \Delta s,$$

$$(Bx)^{\Delta}(t) = -\frac{1}{T} \int_0^T sa(s) f(s,x(s)) \Delta s$$

$$+ \frac{1}{T} \int_0^T (T-s) a(s) f(s,x(s)) \Delta s$$

$$- A \int_0^T G(\eta_i,s) a(s) f(s,x(s)) \Delta s,$$

$$(Bx)^{\Delta \Delta}(t) = -a(t) f(t,x(t)), \quad t \in (0,T).$$  

(32)
By simple computation, we obtain

\[(Bx)(0) - \sum_{i=1}^{m-2} \alpha_i (Bx)(\eta_i) = 0, \quad (Bx)(T) = 0, \quad (33)\]

\[(Bx)^{\Delta} (t) + a(t)f(t, x(t)) = 0. \quad (34)\]

Let

\[x(t) = \min \{k(t), (Bk)(t)\}, \quad \bar{x}(t) = \max \{k(t), (Bk)(t)\}. \quad (35)\]

Obviously \(x(t), \bar{x}(t)\) are well defined, and

\[\bar{x}(t) \leq \bar{x}(t). \quad (36)\]

Since \(BP \subset P\), then for any \(k(t) \in P\), we see that \((Bk)(t) \in P\). Thus there exists positive real number \(m_{Bk}\), such that \((Bk)(t) \geq m_{Bk}k(t)\). From (35) and (36), we know that \(\bar{x}(t) \geq \bar{x}(t) = \min \{k(t), (Bk)(t)\}\)

\[\geq \min \{1, m_{Bk}\} k(t) = m_1k(t), \quad (37)\]

where \(m_1 = \min \{1, m_{Bk}\}\). Therefore \(x, \bar{x} \in P\). Thus \((B\bar{x})(t)\) and \((B\bar{x})(t)\) are well defined, and

\[(B\bar{x})(t) \leq (B\bar{x})(t) \leq (Bm_1k)(t). \quad (38)\]

Since \(B\) is a nonincreasing operator, from (35), we know that \(B\bar{x})(t) \leq (Bk)(t) \leq \bar{x}(t), \quad (39)\]

\[(B\bar{x})(t) \geq (Bk)(t) \geq \bar{x}(t). \quad (40)\]

From (34) and the above discussion, we know that

\[(B\bar{x})^{\Delta} (t) + a(t)f(t, B\bar{x}(t)) \geq (B\bar{x})^{\Delta} (t) + a(t)f(t, \bar{x}(t)) = 0, \quad (41)\]

\[(B\bar{x})^{\Delta} (t) + a(t)f(t, B\bar{x}(t)) \leq (B\bar{x})^{\Delta} (t) + a(t)f(t, \bar{x}(t)) = 0. \quad (42)\]

Equation (33) implies \((B\bar{x})(t)\) and \((B\bar{x})(t)\) satisfy conditions (2). From (38) and (40), we know that

\[\left( x(t), \bar{x}(t) \right) = \left( B\bar{x}(t), (B\bar{x})(t) \right) \quad (43)\]

is a couple of lower and upper solution of the problem (1)-(2), and \(x, \bar{x} \in P\). Therefore

\[\bar{x}, \bar{x} \in C_{rd} [0, T] \cap C^1_{rd} (0, T). \quad (44)\]

Consequently

\[\bar{x}^{\Delta} (t) + a(t)f(t, \bar{x}(t)) \leq 0, \quad t \in (0, T). \quad (45)\]

\[\bar{x}(T) \geq 0, \quad \bar{x}(0) = \sum_{i=1}^{m-2} \alpha_i \bar{x}(\eta_i) \geq 0. \quad (46)\]

\[\square\]

3. Main Results

Theorem 9. Suppose that \((H_1)-(H_3)\) hold. Then the problem (1)-(2) has a unique positive solution \(x^* \in C_{rd}[0, T] \cap C^2_{rd}(0, T)\) satisfying \(x^*(t) \geq \nu k(t)\), where \(\nu\) is a positive constant.

Proof of Theorem 9. We have the following.

(I) Existence of Positive Solution to the Problem (1)-(2). From Lemma 8, we know that the problem (1)-(2) has a couple of lower and upper solution. Let \((\phi(t), \bar{\phi}(t))\) be a couple of lower and upper solution of the problem (1)-(2). Then for any \(t \in (0, T)\), we have that \(k(t) > 0, G(t, s), \phi(t), \bar{\phi}(t)\) are strictly positive continuous function.

Define auxiliary function \(H(t, x)\) and operator \(Q\) as follows:

\[H(t, x) = \begin{cases} f(t, \phi(t)), & \text{if } x < \phi(t), \\ f(t, x), & \text{if } \phi(t) \leq x \leq \bar{\phi}(t), \\ f(t, \bar{\phi}(t)), & \text{if } x > \bar{\phi}(t), \end{cases} \]

\[(44)\]

\[Q_x(t) = \int_0^T G(t, s) a(s) H(s, x(s)) \Delta s + A(T-t) \int_0^T G(s, s) a(s) H(s, x(s)) \Delta s, \quad \forall x \in P. \quad (45)\]

Obviously, we see that \(H(t, x) : (0, T) \times (0, +\infty) \rightarrow [0, +\infty)\) is continuous.

Consider the following second order differential equation \(m\)-point singular boundary value problem:

\[y^{\Delta} (t) + a(t) H(t, y) = 0, \quad t \in (0, T), \quad (46)\]

\[y(T) = 0, \quad y(0) - \sum_{i=1}^{m-2} \alpha_i y(\eta_i) = 0. \quad (47)\]

It is well known that the existence of a positive solution of problem (46) is equivalent to the existence of a nontrivial fixed point of \(Q\) in \(P\).

Now we prove that \(Q\) is a completely continuous operator. From \(\phi(t) \in P\), there exists a positive real number \(m_1\) such that \(\phi(t) \geq m_1k(t)\), for all \(t \in [0, T]\). Combining \((H_2)-(H_3)\) with (44) and (42), we know that

\[\int_0^1 k(s) a(s) f(s, \phi(s)) \Delta s \quad (48)\]
is definitely a finite real number. Denote
\[ \Gamma = \int_0^T a(s) f\left(s, \Phi\left(\frac{s}{s}\right)\right) \Delta s. \]  
(48)

Let constant \( C > 0 \), for all \( x \in \overline{P}_C = \{ x \in P : \|x\| \leq C \} \). Thus, we obtain

\[ (Qx)(t) = \int_0^T G(t, s) a(s) H(s, x(s)) \Delta s + A(T - t) \int_0^T G(t, s) a(s) H(s, x(s)) \Delta s \]
\[ \leq \int_0^T k(s) a(s) H\left(s, \phi\left(\frac{s}{s}\right)\right) \Delta s + A(T - t) \int_0^T G(t, s) a(s) H\left(s, \phi\left(\frac{s}{s}\right)\right) \Delta s \]
\[ \leq \int_0^T k(s) a(s) H(s, m_1 k(s)) \Delta s + A(T - t) \int_0^T k(s) a(s) H(s, m_1 k(s)) \Delta s \]
\[ < +\infty. \]  
(49)

Consequently, \( Q(\overline{P}_C) \) is uniformly bounded.

Now we prove that \( Q \) is compact. Let \( D \subset P \) be a bounded set. Then there exists \( G_1 > 0 \) such that \( \|x\| \leq G_1 \), for all \( x \in D \). It is easy to prove that \( Q(D) \) is a bounded set in \( P \). Since \( G(t, s) \) is continuous on \( [0, T] \times [0, T] \), thus it is uniformly continuous. Therefore, choose \( 0 < \delta < 2e/AT \), for all \( \epsilon > 0 \), and \( t', t'', s \in [0, T] \) such that \( |t' - t''| < \delta \); we have \( |G(t_1, s) - G(t_2, s)| < (\epsilon/2)T^{-1} \). Thus, for any \( x \in D, t', t'' \in [0, T] \) such that \( |t' - t''| < \delta \), we obtain

\[ \left| (Qx)(t') - (Qx)(t'') \right| \]
\[ \leq \int_0^T \left| G(t', s) - G(t'', s) \right| a(s) H(s, x(s)) \Delta s + A \left| t' - t'' \right| \int_0^T k(s) a(s) H(s, x(s)) \Delta s \]
\[ \leq \frac{\epsilon}{2} T^{-1} \int_0^T a(s) H(s, x(s)) \Delta s + \frac{2\epsilon}{AT} \cdot A \cdot \frac{T}{4} \int_0^T a(s) H(s, x(s)) \Delta s \]
\[ \leq \frac{\epsilon}{2} T^{-1} \int_0^T a(s) f\left(s, \phi\left(\frac{s}{s}\right)\right) \Delta s + \frac{\epsilon}{2T} \int_0^T a(s) f\left(s, \phi\left(\frac{s}{s}\right)\right) \Delta s \]
\[ < \frac{\epsilon}{2} T^{-1} \cdot \Gamma + \frac{\epsilon}{2T} \cdot \Gamma = \epsilon. \]  
(50)

Therefore \( Q(D) \) is equicontinuous on \( P \). Then by making use of Arzela-Ascoli theorem \([8] \) on time scale, we know that \( Q(D) \) is relatively compact. Consequently \( Q \) is compact.

On the other hand, let \( \mathcal{B} = \{ x \in P : \phi(t) \leq x(t) \leq \bar{\phi}(t), \text{ for all } t \in [0, T] \} \). Denote \( M_1 = \max_{t \in [0, T]} k(t) \). Then for any \( \epsilon > 0 \), from (49), we know that there exist \( \mu \in (0, T/2) \) such that

\[ \int_0^\mu k(s) a(s) f\left(s, \phi\left(\frac{s}{s}\right)\right) \Delta s \]
\[ + \int_{T-\mu}^T k(s) a(s) f\left(s, \phi\left(\frac{s}{s}\right)\right) \Delta s < \frac{\epsilon}{4(1 + TA)}. \]  
(51)

For \( R > 0 \), since \( H(t, x) \) is continuous on \([\mu, T - \mu] \times [0, R] \), consequently uniformly continuous. Thus there exists \( \mu' > 0 \) satisfying \( \mu > \mu' > 0 \), for any \( t \in [\mu, T - \mu] \), \( x_1, x_2 \in [0, R] \) such that \( |x_1 - x_2| < \mu' \); we have

\[ \left| a(t) \left( H(t, x_1(t)) - H(t, x_2(t)) \right) \right| < \frac{\epsilon}{2M_1 (1 + TA)}. \]  
(52)

Thus, from (51) and (52), for all \( x_1, x_2 \in \mathcal{B} \) such that \( |x_1 - x_2| < \mu' \), we obtain

\[ \left| (Qx_2)(t) - (Qx_1)(t) \right| \]
\[ \leq \int_0^\mu k(s) a(s) \left| H(s, x_1(s)) - H(s, x_2(s)) \right| \Delta s \]
\[ + A(T - t) \int_0^T k(s) a(s) \left| H(s, x_1(s)) - H(s, x_2(s)) \right| \Delta s \]
\[ \leq (1 + TA) M_1 \int_0^\mu k(s) a(s) \left| H(s, x_1(s)) - H(s, x_2(s)) \right| \Delta s \]
\[ + 2 (1 + TA) \left( \int_0^\mu k(s) a(s) f\left(s, \phi\left(\frac{s}{s}\right)\right) \Delta s \right) \]
\[ \leq M_1 (1 + TA) \cdot \frac{\epsilon}{2M_1 (1 + TA)} + 2 (1 + TA) \cdot \frac{\epsilon}{4(1 + TA)} \]
\[ = \epsilon. \]  
(53)

which implies \( Q \) is continuous on \( P \). Consequently \( Q \) is a completely continuous operator.

From Schauder fixed point theorem \([7] \) on time scale, we know that \( Q \) has at least one positive fixed point \( \Phi \in C_{rd}[0, T] \cap C^1_{rd}(0, T) \) in \( P \), and \( \Phi(t) \) satisfies \( \Phi = Q \Phi \). Thus \( \Phi(t) \) satisfies the following differential equation \( m \)-point boundary value problem:

\[ \phi^\Delta(t) + a(t) H(t, \phi(t)) = 0, \]
\[ \phi(0) - \sum_{i=1}^{m-2} \alpha_i \phi(\eta_i) = 0, \quad \phi(T) = 0. \]  
(54)
Now we will prove that $\phi(t) \leq \varphi(t) \leq \overline{\varphi}(t)$, for all $t \in [0, T]$. First, we will prove that $\varphi(t) \leq \overline{\varphi}(t)$, for all $t \in [0, T]$. In fact, if not, then there exists $t^* \in (0, T)$ such that

$$\overline{\varphi}(t^*) < \varphi(t^*) \quad (55)$$

Let $\psi = \overline{\varphi}(t) - \varphi(t)$, for all $t \in [0, T]$. Denote

$$\alpha = \inf \{ t_1 : 0 \leq t_1 < t^*, \psi(t) < 0, t \in (t_1, t^*) \},$$

$$\beta = \sup \{ t_2 : t^* \leq t_2 < T, \psi(t) < 0, t \in (t^*, t_2) \}.$$  

Then $\overline{\varphi}(t) < \varphi(t)$, for all $t \in (\alpha, \beta)$. Thus from (44), we see that $H(t, \varphi(t)) = f(t, \overline{\varphi}(t))$. Combining (43) with (44), we get

$$\overline{\phi}^{\Delta} (t) + a(t) H(t, \overline{\varphi}(t)) = \overline{\phi}^{\Delta} (t) + a(t) f(t, \overline{\varphi}(t)) \leq 0,$$

$$\forall t \in (\alpha, \beta).$$  

(57)

In view of the above discussion and (54), we have $\psi^{\Delta} (t) = \overline{\phi}^{\Delta} (t) - \varphi^{\Delta} (t) \leq 0$. For above $\alpha, \beta, \varphi(t)$, there are two cases:

(i) $\psi(\alpha) = \psi(\beta) = 0$; (ii) $\psi(\alpha) > 0, \psi(\beta) = 0$.

If (1) holds, then $\psi(t) > 0$, for all $t \in [\alpha, \beta]$ which contradicts (55).

If (2) holds, from $\psi(\alpha) > 0$, we know that $\alpha = 0, \psi(t^*) = 0$. With the aid of $\psi(t)$ increasing on $[\alpha, \beta]$ it follows that $\psi(t) \geq 0, t \in [t^*, \beta]$; that is, $\psi(t)$ increasing on $[t^*, \beta]$. From $\psi(\beta) = 0$ it follows that $\psi(t^*) \leq 0$, which contradicts (55). Thus we have $\overline{\varphi}(t) \geq \varphi(t)$.

Similarly, we can verify that $\phi(t) \leq \varphi(t)$. Consequently $\varphi(t)$ is a positive solution of the problem (1)-(2).

(II) Unique Positive Solution of the Problem (1)-(2). Let $x_1(t), x_2(t)$ be two $C^{\alpha}_{rd}[0, T]$ positive solutions of the problem (1)-(2), and $x_1(t) \neq x_2(t)$. Without loss of generality, we assume that $t^* \in (0, T)$ such that $x_2(t^*) > x_1(t^*)$.

Let

$$\alpha = \inf \{ t_1 : 0 \leq t_1 < t^*, x_2(t) > x_1(t), t \in (t_1, t^*) \},$$

$$\beta = \sup \{ t_2 : t^* \leq t_2 < T, x_2(t) > x_1(t), t \in (t^*, t_2) \},$$  

(58)

and $\varphi(t) = x_2(t) - x_1(t)$ for all $t \in [0, T]$. It is easy to see that there are two cases for above $\alpha, \beta, \varphi$: (i) $\varphi(\alpha) = \varphi(\beta) = 0$; (ii) $\varphi(\alpha) > 0, \varphi(\beta) = 0$.

From $t^* \in (\alpha, \beta)$, we have $x_2(t) > x_1(t), f(t, x_2(t)) \leq f(t, x_1(t))$. Thus, $\varphi^{\Delta} (t) = x_2^{\Delta} (t) - x_1^{\Delta} (t) \geq 0$ for all $t \in (\alpha, \beta)$.

Case (i). From $\varphi^{\Delta} (t) > 0$ and $\varphi(\alpha) = \varphi(\beta) = 0$, we obtain $\overline{\varphi}(t) \leq 0, t \in [\alpha, \beta]$, which contradicts $x_2(t^*) > x_1(t^*)$.

Case (ii). From $\varphi(\alpha) > 0$, we know that $\alpha = 0, \varphi(t) = 0$. With the aid of $\varphi(t)$ increasing on $[\alpha, \beta]$, we get that $\varphi(t) \geq 0, t \in [t^*, \beta]$; that is, $\varphi(t)$ is increasing on $[t^*, \beta]$. From $\varphi(\beta) = 0$, we see that $\varphi(t^*) \leq 0$, which contradicts $x_2(t^*) > x_1(t^*)$.

Therefore the problem (1)-(2) has a unique positive solution.

\begin{theorem}
Suppose that $(H_1)-(H_4)$ hold. In addition, one assumes that the following condition is satisfied:

$$\left( H_3 \right) \quad \alpha(t)f(t,r) \neq 0,$$

$$\quad 0 < \int_{0}^{1} a(s)f(s,r,k(s)) \Delta s < +\infty, \quad \forall r > 0. \quad (59)$$

Then, the problem (1)-(2) has a unique positive solution $\varphi \in C^{\alpha}_{rd}[0, T] \cap C^{\beta}_{rd}[0, T]$, and there exist positive real numbers $L > 1 > 0$ such that

$$I(T-t) \leq \varphi(t) \leq L(T-t). \quad (60)$$

\end{theorem}

Proof. By making use of Lemma 8, we know that the problem (1)-(2) has a couple of lower and upper solution. Applying Theorem 9 we see that the problem (1)-(2) has a unique positive solution $\varphi \in C^{\alpha}_{rd}[0, T] \cap C^{\beta}_{rd}[0, T]$. From (H3), we know that $f(\eta, \varphi(\eta))$ is integrable on $(0, T)$. Thus $\varphi^{\Delta}(t)$ is integrable on $(0, T)$. It follows from the fact that $\varphi^{\Delta}(0)$ and $\varphi^{\Delta}(T)$ exist that we see that $\varphi(t)$ is a $C^{\alpha}_{rd}[0, T]$ positive solution of the problem (1)-(2). Clearly, $\varphi(t)$ may be expressed by

$$\varphi(t) = \int_{0}^{T} G(t,s)a(s)f(s,\varphi(s)) \Delta s \quad + A(T-t) \int_{0}^{T} G(\eta, s)a(s)f(s,\varphi(s)) \Delta s. \quad (61)$$

Thus, for any $t \in [0, T]$, we get

$$\varphi(t) \leq A(T-t) \int_{0}^{T} k(\eta) a(s)f(s,\varphi(s)) \Delta s \quad + k(t) \int_{0}^{T} a(s)f(s,\varphi(s)) \Delta s \quad \leq (Ak(\eta) + 1) \int_{0}^{T} a(s)f(s,\varphi(s)) \Delta s(T-t) \quad \leq L(T-t),$$

where $L = (1 + Ak(\eta)) \int_{0}^{T} a(s)f(s,\varphi(s)) \Delta s$.

On the other hand,

$$\varphi(t) \geq A(T-t) \int_{0}^{T} G(\eta, s)a(s)f(s,\varphi(s)) \Delta s \quad \geq A(T-t) \min_{s \in [0,T]} G(\eta, s) \int_{0}^{T} a(s)f(s,\varphi(s)) \Delta s \quad = l(T-t),$$

where $l = A \min_{s \in [0,T]} G(\eta, s) \int_{0}^{T} a(s)f(s,\varphi(s)) \Delta s$. Therefore, from (62) and (63), we see that (60) holds.

\end{proof}
Corollary 11. Suppose that (H_1)-(H_3) hold. In addition, assume that the following condition is satisfied:

\((H_4)\) \(f(t, r) \neq 0, 0 < \int_0^T k(s) f(s, r) ds < +\infty, \) for all \(r > 0.\)

Then the following problem

\[ x^\Delta (t) + f(t, x) = 0, \quad t \in (0, T), \]

\[ x(T) = 0, \quad x(0) - \sum_{i=1}^{m-2} \alpha_i x(\eta_i) = 0 \]  

(64)

has a unique positive solution \(\varphi \in C_{rd}[0, T] \cap C^2_{rd}(0, T),\) and there exist positive constants \(l > 0\) such that \(l(T-t) \leq \varphi(t) \leq L(T-t).\)

Corollary 12. Suppose that (H_1)-(H_2) hold. In addition, assume that the following condition is satisfied:

\((H_5)\) \(f(t, r) \neq 0, 0 < \int_0^T k(s) f(s, r) ds < +\infty, \) for all \(r > 0.\)

Then the problem (64) has a unique positive solution \(\psi \in C_{rd}[0, T] \cap C^2_{rd}(0, T),\) and there exist positive constants \(l > 0\) such that \(l(T-t) \leq \psi(t) \leq L(T-t).\)

If \(a(t)\) is nonsingular at \(t = 0\) or \(t = T, x = 0,\) and for all \(x \geq 0,\) one has \(f(t, x) \leq f(t, 0), t \in (0, T),\) then the following conclusion holds.

Theorem 13. Suppose that \(a \in C_{rd}[0, T], f(t, x) : [0, T] \times [0, +\infty) \rightarrow [0, +\infty)\) is continuous, \(a(t) f(t, r) \neq 0, \) for all \(r \geq 0,\) and \(f(t, x)\) is nonincreasing with respect to \(x,\) for all \(t \in [0, T].\) Then the problem (1)-(2) has a unique positive solution.

Remark 14. Under some weaker condition, we not only establish the existence of positive solution of the problem (1)-(2), but also obtain the uniqueness of the positive solution.

Remark 15. Without the cavity of \(f(t, x)\) and other stronger conditions imposed on \(f(t, x),\) only \(f(t, x)\) nonincreasing with respect to \(x,\) we obtain new results. The main results hold even if the problem is nonsingular.

4. Examples

In this section, we will present two examples to illustrate the main result in this paper.

Example 1. Let \(\mathbb{T} = \{0, 1/4, 1/3\} \cup [1/2, 1].\) Consider the following boundary value problem:

\[ x^{\Delta \Delta} (t) + \frac{1}{\sqrt{t(1-t)x}} = 0, \quad 0 < t < 1, \]

\[ x(1) = 0, \quad x(0) = \frac{1}{3} x\left(\frac{4}{3}\right) + \frac{1}{6} x\left(\frac{2}{3}\right). \]  

(65)

Then, the four-point boundary value problem (65) has at least one positive solution.

Note that \(a(t) = 1, t \in (0, 1), f(t, x) = 1/\sqrt{t(1-t)x}\) is nonincreasing in \(x,\) and \(f(t, x)\) is singular at \(t = 0\) and \(t = 1.\)

Obviously, \((H_1)\) and \((H_2)\) are satisfied. Moreover, for any fixed \(\lambda > 0, (H_3)\) follows immediately from

\[ 0 < \int_0^1 a(t) f(t, \lambda t (1-t)) dt \]

\[ = \int_0^1 \frac{dt}{\sqrt{t(1-t)\lambda t (1-t)}} < +\infty. \]  

(66)

Thus, the existence of a positive solution follows from Theorem 9.

Example 2. Let \(\mathbb{T} = \{0, 1/9, 1/7, 1/6, 1/5, 1/3\} \cup [1/2, 1].\) Consider the following boundary value problem:

\[ x^{\Delta \Delta} (t) + \frac{t}{\sqrt{t(1-t)x}} = 0, \quad 0 < t < 1, \]

\[ x(1) = 0, \quad x(0) = \frac{1}{3} x\left(\frac{1}{3}\right) + \frac{1}{5} x\left(\frac{1}{5}\right) + \frac{1}{7} x\left(\frac{3}{7}\right) + \frac{1}{9} x\left(\frac{5}{9}\right). \]  

(67)

Then, the four-point boundary value problem (65) has at least one positive solution.

Note that \(a(t) = t, t \in (0, 1), f(t, x) = 1/\sqrt{t(1-t)x}\) is nonincreasing in \(x,\) and \(f(t, x)\) is singular at \(t = 0\) and \(t = 1.\)

Obviously, \((H_1)\) and \((H_2)\) are satisfied. Moreover, for any fixed \(\lambda > 0, (H_3)\) follows immediately from

\[ 0 < \int_0^1 a(t) f(t, \lambda t (1-t)) dt \]

\[ = \int_0^1 \frac{dt}{\sqrt{t(1-t)\lambda t (1-t)}} < +\infty. \]  

(68)

Thus, the existence of a positive solution follows from Theorem 9.

Conflict of Interests
