(Received 13 July 2015; published 7 December 2015)

Graphene hosting a pair of collinear adatoms in the phantom atom configuration has density of states vanishing in the vicinity of the Dirac point which can be described in terms of the pseudogap scaling as cube of the energy, \( \Delta \propto \varepsilon^3 \), which leads to the appearance of spin-degenerate bound states in the continuum (BICs) [Phys. Rev. B 92, 045409 (2015)]. In the case when adatoms are locally coupled to a single carbon atom the pseudogap scales linearly with energy, which prevents the formation of BICs. Here, we explore the effects of nonlocal coupling characterized by the Fano factor of interference \( q_0 \), tunable by changing the slope of the Dirac cones in the graphene band structure. We demonstrate that three distinct regimes can be identified: (i) for \( q_0 < q_{c1} \) (critical point) a mixed pseudogap \( \Delta \propto |\varepsilon|, \varepsilon^2 \) appears yielding a phase with spin-degenerate BICs; (ii) near \( q_0 = q_{c1} \) when \( \Delta \propto |\varepsilon|^2 \) the system undergoes a quantum phase transition (QPT) in which the new phase is characterized by magnetic BICs, and (iii) at a second critical value \( q_0 > q_{c2} \) the cubic scaling of the pseudogap with energy \( \Delta \propto \varepsilon^3 \) characteristic to the phantom atom configuration is restored and the phase with nonmagnetic BICs is recovered. The phase with magnetic BICs can be described in terms of an effective intrinsic exchange field of ferromagnetic nature between the adatoms mediated by graphene monolayer. We thus propose a new type of QPT resulting from the competition between two ground states, respectively characterized by spin-degenerate and magnetic BICs.

I. INTRODUCTION

Graphene-based systems are promising candidates for the detection of the so-called bound states in the continuum (BICs) [1,2]. BICs were first theoretically predicted by von Neumann and Wigner in 1929 [3] as quantum states with localized square-integrable wave functions, but having energies within the continuum of delocalized states. The electrons within BICs do not decay into the system continuum; thus these states should be invisible in transport experiments.

The subject experienced revival after the work of Stiller and Herrick in 1975 [4]. Since then, BICs were predicted to appear in a variety of electronic, optical, and photonic systems [1,5,6]. In these systems, effects of Fano interference [7] were proposed as the underlying mechanism for the emergence of BICs and their possible experimental observation. In particular, we recently proposed that BICs can be observed in the system of graphene with two collinear adatoms in the phantom atom configuration [1].

In this work, we show that the setup outlined in Fig. 1 for suspended graphene can undergo a quantum phase transition (QPT) into the state with magnetic BICs if nonlocal graphene-adatom couplings are taken into account. The phenomenon is a consequence of the particular scaling of the local density of states (LDOS) \( D_0 \) on energy \( \varepsilon \) in the vicinity of the Dirac point. The latter is proportional to the quantity known as pseudogap \( \Delta \), related to the intensity of the scattering near the Fermi energy [8,9]. Formation of the magnetic BICs becomes possible only if \( \Delta \propto |\varepsilon|^3 \) similar to the transition reported in Ref. [8] for a pair of quantum dots coupled to metallic leads.

The QPT reported here is driven by a Fano factor of interference \( q_0 \) which can be thus considered as the natural control parameter of the system. It can be tuned by changing the slope of the Dirac cones in the graphene band structure [see Fig. 1(b)]. The magnetic BICs appear within the region inside the critical boundaries \( q_{c1} < q_0 < q_{c2} \), where the dominant scaling law for the pseudogap is quadratic (\( \Delta \propto |\varepsilon|^2 \)). Outside this region, the mixed scaling \( \Delta \propto |\varepsilon|, \varepsilon^2 \) for \( q_0 < q_{c1} \) or cubic scaling \( \Delta \propto |\varepsilon|^3 \) for \( q_0 > q_{c2} \) leads to the formation of spin-degenerate BICs. The transition towards the magnetic BIC state is triggered due to the onset of the effective intrinsic ferromagnetic exchange field \( J_{\text{exch}} \) between the adatoms mediated by the graphene monolayer.

II. MODEL

To give a theoretical description of the setup plotted in Fig. 1, we use the model based on the Anderson Hamiltonian [10,11]:

\[
\mathcal{H}_{2D} = \sum_{\sigma} \int dk (hv_F k) c_{i\sigma}^\dagger c_{i\sigma} + \sum_{j\sigma} \epsilon_{j\sigma} d_{j\sigma}^\dagger d_{j\sigma} + \sum_{j} V d_{j\uparrow}^\dagger n_{dj\downarrow} + \sum_{j\sigma} \int dk w_{j\sigma}^\dagger c_{i\sigma} d_{j\sigma} + \text{H.c.},
\]

\( ^* \)Current address: Institute of Semiconductor and Solid State Physics, Johannes Kepler University Linz, Austria.
with \( v_F \) being Fermi velocity. The graphene monolayer is described by operators \( c_{sk\sigma}^\dagger \left(c_{sk\sigma}\right) \) for creation (annihilation) of electrons in quantum states labeled by the wave number \( k \), spin \( \sigma \), and valley index \( s = 1, 2 \). For the adatoms, \( d_{j\sigma}^\dagger \left(d_{j\sigma}\right) \) creates (annihilates) an electron with spin \( \sigma \) with energy \( \epsilon_{j\sigma} \), where \( j = 1, 2 \) correspond to the upper and lower adatoms, respectively. The third term in Eq. (1) accounts for the on-site Coulomb interaction \( U \) with \( n_{j\sigma\sigma'} = d_{j\sigma}^\dagger d_{j\sigma'} \). Finally, the last term mixes the graphene and the levels \( \epsilon_{j\sigma} \), wherein H.c. gives the Hermitian conjugate of the first part. This mixing is characterized by the coupling \( V_k = \frac{1}{\pi} \sqrt{\frac{2\Omega_0}{\mathcal{N}}} |D| \sqrt{|k|} (1 - q_0 \frac{\hbar v_F k}{D}) \), where \( \mathcal{N} \) is the number of conduction states, \( \Omega_0 \) denotes the unit cell area, and

\[
q_0 = \frac{v_F D}{v_0 f} \tag{2}
\]

is the Fano factor of interference defined according to the results of Ref. [12]. The parameter \( t \) stands for the coupling strength between carbon atoms, while \( v_0 \) and \( v_1 \) represent the host-adatom hybridizations outlined in Fig. 1 and \( D = 7 \) eV denotes the band edge for \( v_F \sim c/300 \). The Fano factor \( q_0 \) can be tuned assisted by a variation of \( v_F \), which enters into \( t = \frac{2\hbar v_F}{c} \) [13] and \( \frac{D}{m} \). The experimental tuning of \( v_F \) can be achieved, for instance, by means of modifying the carrier concentration in suspended graphene [14] [inset of Fig. 1(a)].

The situation \( q_0 = 0 \) corresponds to the scenario in which collinear adatoms are locally side-coupled to a single carbon atom (local coupling regime). Otherwise, \( q_0 \neq 0 \) denotes the hybridization of the adatoms with the three second neighbors of carbons as depicted in Fig. 1 (nonlocal coupling).

To analyze the transport properties of the geometry we consider and look for the existence of the BICs, we should focus on the local density of states of the host (LDOS) and those corresponding for the adatoms (DOS). The former defines the conductance of the device at zero temperature \( T = 0 \) [1]:

\[
G \sim \frac{e^2}{h} \Gamma_{up} \text{LDOS}, \tag{3}
\]

with \( \Gamma_{up} = \pi t^2 \rho_{up}, \rho_{up} \) as the STM tip density of states.

To obtain the value of LDOS probed by the STM tip of Fig. 1, we should consider the tunneling Hamiltonian

\[
H_{\text{tun}} = t_c \sum_{\sigma} \psi_{\text{tip},\sigma}^\dagger \Psi_{\sigma} + \text{H.c.}, \tag{4}
\]

where \( \psi_{\text{tip},\sigma} \) and \( \Psi_{\sigma} \) are respectively fermionic operators for the edge site of the STM tip and

\[
\Psi_{\sigma} = \frac{1}{2\pi} \int \frac{\Omega_0}{\mathcal{N}} \sum_{k} \sqrt{|k|} \left(1 - q_0 \frac{\hbar v_F k}{D}\right) dk \cs_k \sigma \delta_{jl} + \frac{t_c}{t_c} d_{j\sigma} \tag{5}
\]

is the field operator accounting for the quantum state of the graphene site placed right beneath the tip with hopping terms \( (t_{d1} \text{ and } t_c) \); cf. Fig. 1. LDOS then can be computed as

\[
\text{LDOS} = -\frac{1}{\pi} \sum_{\sigma} \Im[G_{\sigma}(\varepsilon^+)] = 2D_0 + \sum_{\sigma j} \Delta\text{LDOS}_{j,\sigma}, \tag{6}
\]

where \( G_{\sigma}(\varepsilon^+) \) is the time Fourier transform of the Green’s function

\[
G_{\sigma} = -\frac{i}{\hbar} \theta(\tau) \text{Tr} \{ \chi_{\sigma}(\tau) \Psi_{\sigma}(0) \} \tag{7}
\]

and

\[
D_0 = \frac{|\varepsilon|}{D^2} \left(1 - q_0 \frac{\varepsilon}{D}\right)^2 \tag{8}
\]

is the graphene DOS; \( \Delta\text{LDOS}_{j,\sigma} \) stands for the part induced by the adatoms (see detailed derivation for it in the Appendix).

It is worth mentioning that \( \Delta\text{LDOS}_{j,\sigma} \) for \( j \neq l \) represents electronic waves of a given spin \( \sigma \) that travel forth and back between the upper and lower adatoms shown in Fig. 1(a), which for a specific energy \( \varepsilon \) become phase shifted by \( \pi \) (Fano dip) with respect to the waves scattered by the adatoms, which are described by \( \Delta\text{LDOS}_{j,\sigma} \). As discussed in Ref. [1], such scattering process then provides a mechanism of the

FIG. 1. (Color online) (a) Side view: two adatoms labeled by 1 (upper) and 2 (lower) placed collinear to a carbon atom beneath an STM tip in suspended graphene (inset). (b) Top view: the adatoms are coupled to the carbon atom beneath them and its nearest neighbors. The relative strength of these couplings define the Fano factor of interference \( q_0 \), playing the role of the natural control parameter of the system. It can be tuned by varying the slope of the Dirac cones in the graphene band structure (inset).
emergence of BICs. This effect can be captured in the detailed derivation of LDOS appearing in the Appendix.

According to the Appendix, the evaluation of $\Delta $LDOS$_{j/l}$ depends on the Green’s functions $\tilde{G}_{ld\sigma,d\sigma}$, $\langle j = 1, 2 \text{ and } l = 1,2 \rangle$ for the adatoms. Additionally, to perceive the BICs emergence in our system, we should know the density of states $\text{DOS}^n_{j/l}$ of these adatoms, which are determined as follows:

$$\text{DOS}^n_{j/l} = -\frac{1}{\pi} \text{Im} \langle \tilde{G}_{ld\sigma,d\sigma} \rangle.$$  

(9)

Thus both $\Delta $LDOS$_{j/l}$ and $\text{DOS}^n_{j/l}$ can be found by employing the Hubbard I approach [15] at $T = 0$, since the determined Hubbard bands match with those obtained via the numerical renormalization group, in particular, for graphene with a single adatom [16]. As a result, we can safely extrapolate the Hubbard I method to our graphene system. We start employing the equation-of-motion method to a single particle retarded Green’s function of an adatom in time domain $\tilde{G}_{ld\sigma,d\sigma} = -\frac{i}{\hbar} \theta(t) \text{Tr}[\tau_2 d(d, \tau) d(l, 0)]_+$, where $\theta(t)$ is the Heaviside function, $\tau_2$ is the density matrix of the system described by the Hamiltonian of Eq. (1), and $\{ \cdots , \cdots \}$ is the anticommutator between operators taken in the Heisenberg picture. Performing elementary algebra one obtains in the energy domain

$$(\varepsilon^+ - \varepsilon_{ld}) \tilde{G}_{ld\sigma,d\sigma} = \delta_{lj} + \sum_n \tilde{G}_{ld\sigma,d\sigma} + U \tilde{G}_{ld\sigma,d\sigma},$$  

(10)

where $\varepsilon^+ = \varepsilon + i0^+$ and

$$\Sigma = \sum_j \int d\lambda \frac{v_{\lambda}}{\varepsilon^+ - \hbar \omega_k} = -\frac{v^2}{D^2} \delta \left(1 - q_0 - \frac{\varepsilon}{D} \right)^2 \ln \left| \frac{D^2 - \varepsilon^2}{\varepsilon^2} \right| + \frac{v^2_0}{D} \left(2 - q_0 \frac{\varepsilon}{D} \right) - i\Delta $$  

(11)

is the self-energy. Its imaginary part $\Delta$ is proportional to the scattering rate of the quasiparticles and is known as pseudogap. The latter is proportional to the local density of states of the host $D_\sigma$ given by Eq. (8), i.e., $\Delta = \pi v_0^2 D_\sigma$ [8,9]. Thus

$$\Delta = \frac{\pi v_0^2}{D^2} |\varepsilon|^2 \left(1 - q_0 - \frac{\varepsilon}{D} \right)^2,$$  

(12)

which depending on the value of the Fano parameter, the main contribution to the pseudogap can be linear, cubic, or quadratic. As we will see in the Discussion section, the latter situation is of particular interest, since magnetic BICs are formed in this case.

In Eq. (10) $\tilde{G}_{ld\sigma,d\sigma}$ is a two particle Green’s function composed by four fermionic operators, obtained from the time Fourier transform of $\tilde{G}_{ld\sigma,d\sigma} = -\frac{i}{\hbar} \theta(t) \text{Tr}[\tau_2 d(d, \tau) d(l, 0)]_+$, with $n_{ld\sigma} = d_{ld\sigma}^\dagger d_{ld\sigma}$ and spin $\sigma$ (opposite to $\sigma$). Thus we first calculate the time derivative of $\tilde{G}_{ld\sigma,d\sigma}$, and then its time Fourier transform, which leads to

$$(\varepsilon^+ - \varepsilon_{ld} - U) \tilde{G}_{ld\sigma,d\sigma} = \delta_{lj} (n_{ld\sigma}) + \sum_j \int d\lambda \frac{v_{\lambda}}{\varepsilon^+ - \hbar \omega_k} \left(\tilde{G}^\dagger_{ld\sigma,d\sigma} G_{ld\sigma,d\sigma} + \tilde{G}^\dagger_{ld\sigma,d\sigma} G_{ld\sigma,d\sigma} \right).$$  

(13)

FIG. 2. Occupation numbers given by Eq. (14) for spin-up and spin-down states of the adatoms as a function of $q_0$. Expressed in terms of new Green’s functions of the same order of $\tilde{G}_{ld\sigma,d\sigma}$, and the occupation number $\langle n_{ld\sigma} \rangle$ determined by

$$\langle n_{ld\sigma} \rangle = -\frac{1}{\pi} \int_{-D}^{D} \text{Im} (\tilde{G}_{ld\sigma,d\sigma}) d\varepsilon.$$  

(14)

We highlight that, for the quadratic pseudogap, the self-consistent evaluation of Eq. (14) reveals a range of magnetic solutions with $\langle n_{d\uparrow} \rangle \neq \langle n_{d\downarrow} \rangle$ for the values of $q_0$, lying in the range between two critical points $q_1$ and $q_2$. Outside the magnetic region, i.e., for different scalings of the pseudogap ($\Delta \propto |\varepsilon_{d\uparrow}|^2$ for $q_0 < q_1$, and $\Delta \propto |\varepsilon_{d\downarrow}|^2$ for $q_0 > q_2$), Eq. (14) has nonmagnetic solutions with $\langle n_{d\uparrow} \rangle = \langle n_{d\downarrow} \rangle$ only. This point will be addressed in detail in Sec. III of the paper (see in particular Fig. 2).

Furthermore, by employing the Hubbard I approximation, we decouple the Green’s functions in the right-hand side of Eq. (13) as performed in Ref. [1]. This procedure enables us to solve the system of Green’s functions within Eq. (10), leading to $\tilde{G}_{ld\sigma,d\sigma} = \frac{\lambda_{ld\sigma}^j}{\varepsilon - \varepsilon_{ld} - \Sigma_{ld\sigma}}$, where $\lambda_{ld\sigma}^j = (1 + \frac{U(n_{ld\sigma})}{\varepsilon - \varepsilon_{ld} - \Sigma_{ld\sigma}})$, and

$$\hat{\Sigma}_{ld\sigma}^j = \Sigma + \frac{\lambda_{ld\sigma}^j}{\varepsilon - \varepsilon_{ld} - \Sigma} \frac{\Sigma^2}{\varepsilon - \varepsilon_{ld} - \Sigma}$$  

(15)

is the total self-energy, with $\tilde{j} = 2,1$ respectively for $j = 1,2$ in order to identify distinct adatoms and $\tilde{G}_{ld\sigma,d\sigma}$ are mixed Green’s functions.

III. RESULTS AND DISCUSSION

In the simulations we adopt $T = 0$ and the set of parameters [1]; $\varepsilon_{jd} = \varepsilon_d = -0.07D$, which is feasible in suspended graphene [inset of Fig. 1(a)] [14] and $U = v_0 = -2\varepsilon_d$. Additionally, to avoid that BICs decay into the continuum, we use $\varepsilon_d/\kappa < 0$; otherwise, it leads to experimental detection of BICs by means of the so-called quasi-BICs [1].

In Fig. 2 three distinct regions in the occupation numbers of Eq. (14) for $j = 1,2$ appear identified by their corresponding pseudogaps $\Delta$ [Eq. (12)]: the nonmagnetic regions correspond to small or big Fano factors appear to be divided by a magnetic central domain delimited by the critical values $q_{1,2}$. At critical values, abrupt jumps in the occupation
numbers point out the existence of a QPT connected with the spin degree of freedom. Panel (a) of Fig. 3 presents the DOS corresponding to the regime \( q_0 = 0.8 < q_{c1} \) where one can clearly see resolved and spin-degenerate peaks in Eq. (9) for the DOSs_{jj}. In Fig. 3(b) spin-polarized peaks emerge when the Fano factor is placed within the boundaries \( q_{c1} < q_0 = 1.2 < q_{c2} \), while in panel (c) the case of \( q_0 = 2.0 \) corresponds to the limit of the phantom atom considered in detail in Ref. [1] for which spin degeneracy is recovered.

To demonstrate that the system possesses BICs, we compare the density of states DOS_{jl} for adatoms shown in Fig. 3 with the host local density of states \( \Delta \text{LDOS}_{jl} \) depicted in Fig. 4. As one can see, both quantities reveal pronounced peaks (resonant states) placed at the same positions. Particularly in panels (a) and (b) of Fig. 4 with \( q_0 = 0.8 \), we observe as aftermath of Eq. (A13) degenerate spin-up and -down components for the Fano dips of \( \Delta \text{LDOS}_{jl} (l \neq j) \) interfering destructively with the peaks found in \( \Delta \text{LDOS}_{js} \). As this interference is completely perfect, BICs emerge at the positions marked by vertical lines crossing panels (a), (b), and (c) of this figure. In panel (c) of the same figure, the total LDOS of Eq. (6) reveals absence of peaks at those places in which such a destructive interference occurs within panels (a) and (b). The aforementioned positions without peaks in Fig. 4(c) thereby give rise to BICs: the total LDOS that determines the conductance does not catch the same peaks found in Fig. 3(a) for the adatoms. Thus the aforementioned invisibility of such resonant states points out that electrons with opposite spins stay equally trapped within these adatoms when \( q_0 < q_{c1} \) and the pseudogap scales as \( \Delta \propto |\epsilon|^2 \).

Panels (a), (b), and (c) of Fig. 5 correspond to the case \( q_{c1} < q_0 = 1.2 < q_{c2} \) where magnetic solutions become possible, since the pseudogap is ruled by \( \Delta \propto |\epsilon|^2 \). The position of magnetic BICs is denoted by vertical dashed lines. Consequently, in the domain \( q_{c1} < q_0 < q_{c2} \), the novelty due to a nonlocal coupling between graphene and collinear adatoms lies on the possibility of tuning the spin of the electrons trapped in the BICs of the adatoms. Such a feature yields an emerging based suspended graphene spintronics, in which a spin filter of BICs rises as a feasible application. Outside the critical domain, just spin-degenerate BICs exist.

Let us now present the physical arguments that elucidate the emergence of the reported magnetic BICs, which is indeed triggered by a QPT. Similar QPT appearing due to the quadratic scaling of the pseudogap \( \Delta \propto |\epsilon|^2 \) and related breaking of the spin degeneracy was discussed in Ref. [8], where a double dot system was explored. In regard of this dot setup, we highlight that the pseudogap \( \Delta \propto |\epsilon|^2 \) is only revealed to be present after performing a mapping of the original Hamiltonian into an effective model, in particular, under restricted constraints. On the other hand, we demonstrate that graphene emerges as the natural platform wherein the pseudogap of Eq. (12) includes not only the regime \( |\epsilon|^2 \), but also \( |\epsilon|^3 \), \( |\epsilon|^2 \), and \( |\epsilon|^3 \), just due to the nonlocal adatom-graphene coupling. These regimes are accessible by means of the tuning of the Fano factor \( q_0 \), which here is proposed to be practicable by developing the Fermi velocity engineering [14]. Moreover, the nonlocal coupling assumption improves the emulation of the experimental reality,
Zeeman-like splitting of the levels $\varepsilon_d$ merged peaks of Eq. (9) for the adatoms DOS towards the resolved peaks. (b) QPT due to an abrupt spin splitting of the peaks.

since the standard case of local coupling regime, which is widely employed in the literature, is indeed ideal and hides completely the reported QPT.

Figure 6 illustrates how spin-resolved DOS of the adatoms depend on the Fano parameter. The variation of $q_0$ in the wide range below the critical value $q_{c1} \approx 1.1766$ shifts the position of the peaks corresponding to opposite spin components equally, as it is shown in the upper panel. However, above the critical value the spin splitting abruptly appears as it is shown at the lower panel of the figure, which clearly indicates that the system undergoes a QPT. The abrupt appearance of the spin splitting is intimately connected with the steplike behavior observed in the occupation numbers shown in Fig. 2. Note that the increase of the Fano factor above the second critical value $q_{c2}$ leads to the recovering of the spin degeneracy as the regime of the phantom atom with cubic scaling of the pseudogap $\Delta \propto |\epsilon|^3$ is achieved.

Within the critical boundaries $q_{c1} < q_0 < q_{c2}$, the quantity $\text{Re}(\Sigma_{j}^{\text{exch}} - \Sigma) \equiv J^{\text{exch}}$ from Eq. (15) plays the role of a Zeeman-like splitting of the levels $\varepsilon_j$ in the adatoms. This splitting arises from an intrinsic exchange field $J^{\text{exch}}$ between the adatoms intermediated by the graphene monolayer. Its value is ruled by the system natural control parameter, namely the Fano factor $q_0$, which drives the graphene system towards a QPT. As the upper and lower adatoms magnetize equally, cf. Fig. 2, the coupling between them is revealed as ferromagnetic. Note that the dependence of the effective field on the Fano parameter is nonmonotonous: it drops abruptly when $q_0 = q_{c2} \approx 1.3582$.

IV. CONCLUSIONS

In summary, we have proposed a setup based on the graphene-adatom system in which magnetic BICs are triggered by a quantum phase transition in the region of the quadratic scaling of the pseudogap with energy, $\Delta \propto |\epsilon|^2$. The control parameter which drives this transition is a Fano factor of interference tunable by changing the slope of the Dirac cones in graphene band structure.

APPENDIX: LDOS DERIVATION

To obtain the analytical expressions of the LDOS given by Eq. (6) appearing in the conductance of Eq. (3), we begin by applying the equation-of-motion approach to $g_\sigma = -\frac{i}{\hbar} \theta(\tau) \text{Tr}[\hat{g}_{2D}[\Psi_\sigma(\tau), \Psi_\sigma^\dagger(0)]_+]$, with Eq. (5) rewritten as

$$\Psi_\sigma = \frac{1}{2\pi} \sqrt{\frac{\pi \Omega_0}{N}} \sum_k \int |k| \left(1 - q_0 \frac{\hbar v F k}{D}\right) dk c_{sk\sigma}$$

$$+ \left(\pi D_0 v_0\right) \sum_j C_j d_{j\sigma},$$

(A1)

expressed in terms of $C_j = \left(\pi D_0 v_0\right)^{-1} (t_d/\tau) \delta_{j1}$. Substituting Eq. (A1) in $g_\sigma$, one finds

$$g_\sigma = \left(\frac{1}{2\pi} \sqrt{\frac{\pi \Omega_0}{N}}\right)^2 \sum_{k \ell} \int |k| \left(1 - q_0 \frac{\hbar v F q}{D}\right) dk$$

$$\times \sqrt{|q|} \left(1 - q_0 \frac{\hbar v F q}{D}\right) dq g_{c_{sk\sigma}c_{\ell\sigma}^\dagger} + \left(\pi D_0 v_0\right) \sum_j C_j$$

$$\times \left(\frac{1}{2\pi} \sqrt{\frac{\pi \Omega_0}{N}}\right) \int |k| \left(1 - q_0 \frac{\hbar v F k}{D}\right) dk$$

$$\times \left(\hat{g}_{d_{j\sigma}c_{sk\sigma}} + \hat{g}_{c_{ell\sigma}d_{j\sigma}}\right) + \left(\pi D_0 v_0\right)^2 \sum_{jl} C_j C_l g_{d_{jl}d_{ij}},$$

(A2)

with the new Green’s functions $\hat{g}_{c_{sk\sigma}c_{\ell\sigma}^\dagger}$, $\hat{g}_{d_{j\sigma}c_{sk\sigma}}$, and $\hat{g}_{c_{ell\sigma}d_{j\sigma}}$ to be determined. To this end, we first consider $g_{c_{sk\sigma}c_{\ell\sigma}^\dagger} = -\frac{i}{\hbar} \theta(\tau) \text{Tr}[\hat{g}_{2D}[c_{sk\sigma}(\tau), c_{\ell\sigma}^\dagger(0)]_+]$, whose time derivative $\partial_t \equiv \frac{\partial}{\partial \tau}$ gives

$$\partial_t \hat{g}_{c_{sk\sigma}c_{\ell\sigma}^\dagger} = -i \frac{\hbar}{\theta(\tau) \text{Tr}[\hat{g}_{2D}[c_{sk\sigma}(\tau), c_{\ell\sigma}^\dagger(0)]_+}]$$

$$-i \frac{\hbar}{\theta(\tau)} \hat{g}_{c_{sk\sigma}c_{\ell\sigma}^\dagger} - i \sum_j V_j \hat{g}_{d_{j\sigma}c_{sk\sigma}^\dagger},$$

(A3)

where we have used

$$i \hbar \partial_t c_{sk\sigma}(\tau) = [c_{sk\sigma}, \hat{H}_{2D}]$$

$$= [\hbar v F k] c_{sk\sigma}(\tau) + \sum_j V_j d_{j\sigma}(\tau).$$

(A4)

In the energy domain after performing the time Fourier transform, we solve Eq. (A3) for $\hat{g}_{c_{sk\sigma}c_{\ell\sigma}^\dagger}$, and obtain

$$\hat{g}_{c_{sk\sigma}c_{\ell\sigma}^\dagger} = \frac{\delta(k - q) \delta_{\ell\sigma}}{\epsilon^+ - \hbar v F k} + \sum_j \frac{V_j}{\epsilon^+ - \hbar v F k} \delta_{j\sigma} c_{sk\sigma}^\dagger.$$  

(A5)
Notice that we also need to calculate the mixed Green’s function \( G_{d,\sigma} \). We then define the advanced Green’s function \( \mathcal{F}_{d,\sigma} = \frac{i}{\hbar}(\tau)\text{Tr}[^2d]\{d^\dagger_{\sigma}(0),c_{\sigma\sigma}(\tau)\} \), whose equation of motion reads

\[
\partial_\tau \mathcal{F}_{d,\sigma} = -\frac{i}{\hbar}\hat{\mathcal{H}}(\tau)\text{Tr}[^2d]\{d^\dagger_{\sigma}(0),c_{\sigma\sigma}(\tau)\} + i \sum_l V_l \mathcal{F}_{d_l,\sigma} d_{\sigma l}, \tag{A6}
\]

where we have used once again Eq. (A4), interchanging \( k \leftrightarrow q \). The Fourier transform of Eq. (A6) leads to

\[
e^{-\tau \mathcal{F}}_{d,\sigma} = (\hbar v_F q) \mathcal{F}_{d,\sigma}^{q} + \sum_l V_q \mathcal{F}_{d_l,\sigma}^{q l} , \tag{A7}
\]

with \( \varepsilon^->_\varepsilon^+ = \varepsilon - i0^+ \). Applying the property \( \mathcal{G}_{d,\sigma} = (\mathcal{F}_{d,\sigma})^* \) on Eq. (A7), we show that

\[
\mathcal{G}_{d,\sigma} = \sum_l \frac{V_l}{\hbar v_F q} \mathcal{G}_{d_l,\sigma} , \tag{A8}
\]

and, analogously,

\[
\mathcal{G}_{d,\sigma} = \sum_l \frac{V_l}{\hbar v_F q} \mathcal{G}_{d_l,\sigma} . \tag{A9}
\]

Now we substitute Eq. (A9) into Eq. (A5) and the latter, together with Eqs. (A10) and (11) for the self-energy split as

\[
\Sigma = \sum_s \int dk \frac{\frac{1}{\pi} \text{Im} \mathcal{G}_{s,\sigma}}{\varepsilon + i/\hbar v_F k} = \pi v_F^2 D_0 (\mathcal{A}_j - iB_j) , \tag{A11}
\]

into Eq. (A2) in the energy domain, which results in

\[
\mathcal{G}_s = \left( \frac{1}{2\pi} \sqrt{\frac{\pi \Sigma_0}{\mathcal{N}}} \right) \sum_s \int \left( 1 - q_0 \frac{\hbar v_F k}{D} \right)^2 dk \frac{1}{\epsilon^+ - \epsilon_k} + (\pi D_0 v_0)^2 \sum_{jl} (\mathcal{A}_j - iB_j) \mathcal{G}_{d_j,\sigma} (\mathcal{A}_l - iB_l) + (\pi D_0 v_0)^2 \sum_{jl} \mathcal{C}_j (\mathcal{A}_l - iB_l) (\mathcal{G}_{d_j,\sigma} + \mathcal{G}_{d_l,\sigma}) + (\pi D_0 v_0)^2 \sum_{jl} \mathcal{C}_j \mathcal{C}_l \mathcal{G}_{d_j,\sigma} . \tag{A12}
\]

Thus after some algebra via the evaluation of \(-\frac{1}{\pi} \sum_s \text{Im}(\mathcal{G}_s)\), we determine Eq. (6) as the LDOS probed by the STM tip, with

\[
\Delta \text{LDOS}_{j\sigma} = -\left( \pi v_F^2 D_0^2 \right) \text{Im}(\mathcal{A}_j - iB_j) \mathcal{G}_{d_j,\sigma} (\mathcal{A}_j - iB_j) , \tag{A13}
\]

with \( A_j = \frac{1}{\pi v_0^2 D_0} \text{Re} \Sigma + \delta_j (\pi^2 v_0^2 D_0)^{-1/2} (t_d / t_c) \) and \( B_j = -\frac{1}{\pi v_0^2 D_0} \text{Im} \Sigma \).
