Abstract

We present a method that uses alternation data to add new entries to an existing bilingual valency lexicon. If the existing lexicon has only one half of the alternation, then our method constructs the other half. The new entries have detailed information about argument structure and selectional restrictions. In this paper we focus on one class of alternations, but our method is applicable to any alternation. We were able to increase the coverage of the causative alternation to 98%, and the new entries gave an overall improvement in translation quality of 32%.

1 Introduction

Recently, deep linguistic processing, which aims to provide a useful semantic representation, has become the focus of more research, as parsing technologies improve in both speed and robustness (Uszkoreit, 2002). In particular, machine translation systems still mainly rely on large hand-crafted lexicons. The knowledge acquisition bottleneck, however, remains: precise grammars need information-rich lexicons, such as valency dictionaries, which are costly to build and extend. In this paper, we present a method of adding new entries to an existing bilingual valency dictionary, using information about verbal alternations.

The classic approach to acquiring lexical information is to build resources by hand. This produces useful resources but is expensive. This is still the approach taken by large projects such as FrameNet (Baker et al., 1998) or OntoSem. Therefore, there is a need to extend these handmade resources quickly and economically. Another approach is to attempt to learn information from corpora. There has been much research based on this, but due to the inevitable errors, there are few examples of lexicons being constructed fully automatically. Korhonen (2002) reports that the ceiling on the performance of mono-lingual subcategorization acquisition from corpora is generally around 80%, a level that still requires manual intervention. Yet another approach is to combine knowledge sources: for example to build a lexicon and then try to extend it using corpus data or to enrich monolingual data using multilingual lexicons (Fujita and Bond, 2002).

The aim of this research is not to create a lexicon from scratch, but rather to add further entries to an existing lexicon. We propose a method of acquiring detailed information about predicates, including argument structure, semantic restrictions on the arguments and translation equivalents. It combines two heterogeneous knowledge sources: an existing bilingual valency lexicon (the seed lexicon), and information about verbal alternations.

Most verbs have more than one possible argument structure (subcat). These can be regularized into pairs of alternations, where two argument structures link similar semantic roles into different subcats. Levin (1993) has identified over 80 alternation types for English, and these have been extended to cover 4,432 verbs in 492 classes (Dorr, 1997). In this paper, we will consider alternations between transitive (Vt) and intransitive (Vi) uses of verbs, where the subject of the intransitive verb (S) is the same as the object of the transitive verb (O) (e.g. the acid dissolved the metal ⇔ the metal dissolved (in the acid)) (Levin, 1993, 26–33)). We call the subject of the transitive verb A (ergative) and this alternation the S=O alternation.

Figure 1 shows a simplified example of an alternating pair in a bilingual valency dictionary (the valency lexicon from the Japanese-to-English machine translation system ALT-J/E (Ikehara et al., 1991)). This includes the subcategorization frame and selectional restrictions. As shown in Figure 1, Japanese, unlike English, typically morphologically marks the transitivity alternation.

We chose the S=O alternation because it is one
of the most common types of alternations, making up 34% of those discovered by Bond et al. (2002) and has been extensively studied. The method we present, however, can be used with any alternation for which lists of alternating verbs exist.

2 Resources
We use two main resources in this paper: (1) a seed lexicon of high quality hand-made valency entries; and (2) lists of verbs that undergo one or more S=O alternations.

The alternation list includes 449 native Japanese verbs that take the S=O alternation, based on data from Jacobsen (1981), Bullock (1999) and the Japanese/English dictionary EDICT (Breen, 1995). Each entry consists of a pair of Japanese verbs with one or more English glosses. Expanding out the English results in 839 Japanese-English pairs in all. Some examples are given in Table 1.

Table 1: Verbs Undergoing the S=O Alternation

As a seed lexicon, we use the valency dictionary (Ikehara et al., 1997) from the Japanese-to-English machine translation system ALT-J/E. It consists of linked pairs of Japanese and English verbs. There are 5,062 Japanese verbs and 11,214 entries (ignoring all idiomatic and adjectival entries). Verb entries in both languages have information about the argument structure (subcat) of the verb. In addition to the core arguments, adjunct cases are added to many patterns to help in disambiguation.

1 This is common in large NLP lexicons, such as COM-LEX (Grishman et al., 1998). For example, the COMLEX 3.0 entry for gather notes that it cooccurs with PPs headed by around, inside, with, in and into.
the meaning, and thus the more restrictive the SR.

We calculate the similarity between two SRs as the minimum distance (MD), measured as links in the ontology. If the SRs share at least one semantic class then the MD is zero. In this case, we further classified the SRs which are identical into “0 (Same)”.

For example, in Figure 1, the MD between S and O is “0 (Same)” because they have the same SR: \( \text{stuff} \). The MD between A and S is two because the shortest path from \( \text{artifact} \) to \( \text{stuff} \) traverses two links \( \text{artifact} \subseteq \text{inanimate} \subseteq \text{stuff} \).

Figure 2 shows the MD between O and S, and A and S. The selectional restrictions are very similar for O and S: 30.1% have identical SRs, distance is zero for 27.5% and distance one is 28.3%. However, for A and S, the most common case is distance one (26.7%) and then distance two (21.5%). Although O and S are different syntactic roles, their SRs are very similar, reflecting the identity of the underlying semantic roles.

![Figure 2: The Minimum Distance of Selectional Restrictions](image)

Next, we examine whether A, O, and S are \( +\text{sentient}, +\text{volition} \) or not. In the GoiTaikei hierarchy, semantic classes subsumed by agent are \( +\text{sentient}, +\text{volition} \). A was very agentitive, with 60.1% of the SRs being subsumed by agent. The most frequent SR for A is \( \text{agent} \) itself (41.4%). S and O are less agentitive, with 13.9% and 14.1% of their respective selectional restrictions being agentitive. This data supports the hypothesis in Kilgarriff (1993).

In summary, the SRs of S and O are not identical, but very similar. In comparison, A is more agentitive, and not closely linked to either.

### 3.2 Comparison of Japanese and English

From the point of view of constructing bilingual lexical entries, if the English main verb can translate both Japanese entries, then it is possible to automatically construct a usable English translation equivalent along with the Japanese alternation. In order to see how often this is the case, we compare Japanese and English alternations and investigate the English translations in the alternation list.

We divide the entries into five types in Table 2. The first three are those where the main English verb is the same. The most common type (30.0%) is made up of English unaccusative verbs which also undergo the S=O alternation [S=0]. The next most common (19.8%) is entries where the Japanese intransitive verb can be translated by making the transitive verb’s English translation passive [passive]. In the third type (6.5%) the English is made transitive synthetically [synthetic]: a control verb (normally make) takes an intransitive verb or adjective as complement. The last two are those where either different translations are used (42.8%), or the same English verb is used but the valency change is not one of those described above.

The first three rows of Table 2 show the verbs whose alternate can be created automatically, 56.3% of the total. This figure is only an approximation, for two reasons. The first is that the translation may not be the best one, most verbs can have multiple translations, and we are only creating one. The second is that this upper limit is almost certainly too low. For many of the alternations, although our table contained different verbs, translations using identical verbs are also acceptable. In fact, most transitive verbs can be made passive, and most intransitive verbs embedded in a causative construction, so this alternative is always possible (and is also possible for Japanese). However, if the Japanese uses a lexical alternation, it is more faithful to link it to an English lexical alternation when possible.

### 4 Method of Creating Valency Entries

In this section we describe how we create new alternating entries. Given a verb, with dependents N_i, and an alternation that maps some or all of the N_i, we can create the alternate by analogy with existing alternating verbs. The basic flow of
creating valency entries is as follows.

- For each dependent $N_i$
  - if $N_i$ participates in the alternation
    - map to it
  - else delete $N_i$
  - else transfer [non-alternating dependent]

- If the alternation requires a dependent not in the source
  - Add the default argument

We use the most frequent argument in existing valency entries as a default. Specific examples of creating $S=O$ alternations are given in the next section.

Although we only discuss the selectional restrictions and subcat information here, we also map the verb classes (given as verbal semantic attributes (Nakaiwa and Ikehara, 1997)). The mapping for the dependents in the alternation can be taken from existing lexical resources (Dorr, 1997), learned from corpora (McCarthy, 2000) or learned from existing lexicons (Bond et al., 2002).

### 4.1 Target

In this experiment, we look at one family of alternations, the $S=O$ alternation. The candidate words are thus intransitive verbs with no transitive alternate, or transitive entries with no intransitive alternate. Alternations should be between senses, but the alternation list is only of words. Many of the candidate words (those that have an entry for only one alternate) have several entries. Only some of these are suitable as seeds. We don’t use entries which are intransitive lemmas but have an accusative argument, which are intransitive (or transitive) lemmas but have an intransitive translation (or intransitive), or which have both topic and nominative, such as (1), where the nominative argument is incorporated in the English translation.

(1) N1: animals $\rightarrow$ N3: (“力”) $\rightarrow$
N1: ha N3: “chikara” ga
N1: TOP N3: power NOM

There are 115 entries (37 lemmas) which have only intransitive entries and 81 entries (25 lemmas) which have only transitive entries which are in our reference list of alternating verbs. We create intransitive entries using the existing transitive entries, and transitive entries using the existing intransitive entries.

### 4.2 Creating the Japanese subcat and SRs

In creating the intransitive entries from the transitive entries, we map the $O$'s SRs onto the $S$'s SRs, and change the case marker from accusative to nominative. We delete the $A$ argument, and transfer any other dependents as they are.

In creating the transitive entries, we map the intransitive $S$'s SRs onto the new $O$'s SRs, and give it an accusative case-marker. If the intransitive entry has a demoted subject argument (where the Japanese case-marker is $ni$ and the English preposition is $by$), we promote it to subject and use its SR for $A$. Otherwise we add a causative argument as ergative subject ($A$) with a default SR of $h$ and a nominative case-marker. We show an example in Figure 3.

### 4.3 Creating the English Equivalents

The English translation can be divided into three types: $S=O$, passive and synthetic. Therefore it is necessary to judge which type is appropriate for each entry, and then create the English. This judgement is shown in Figure 4. To judge whether an English

5 Evaluation
A total of 196 new entries were created for 62 verbs (25 Vi + 37 Vt) using the method outlined in § 4. We evaluated the quality by using the new entries in a machine translation system.

5.1 Translation-Based Evaluation
We evaluated the quality of the created entries in a translation-based regression test. We got two example sentences using each verb from Japanese newspapers and web pages: this gave a total of 124 test sentences. We translated the test sentences using ALT-J/E, both with (with) and without (w/out) the new entries.

Translations that were identical were marked no change (the system translates with a simple word dictionary if it has no valency entry). Translations that changed were evaluated by people fluent in both languages (two thirds by Japanese native speakers and one third by an English native speaker, not the authors). The translations were randomly presented to the evaluators labeled by A and B. Therefore evaluators did not know whether a translation is with or w/out. The translations were placed into three categories: (i) A is better than B, (ii) A and B are equivalent in quality, and (iii) A is worse than B. For example in (2), the evaluation was (iii). In this case A is w/out and B is with, so the new entry has improved the translation.

Table 3 shows the evaluation results, split into those for transitive and intransitive verbs. The most common result was that the new translation was better (46.0%). The quality was equivalent for 13.7% and worse for 14.5%. The overall improvement was 31.5% (46.0 - 14.5).

Extending the dictionary to include the missing alternations gave a measurable improvement in translation quality.

5.2 Lexicographer’s Evaluation
A manual analysis of a subset of the created entries was carried out by expert lexicographers familiar with the seed lexicon (not the authors). They found three major source of errors. The first was that alternation is a sense based phenomenon. As we built alternations for all patterns in the seed dictionary, this resulted in the creation of some spurious patterns. An example of an impossible entry is torawareru “be caught”, translated as be picked up with the inappropriate semantic restriction (concrete,material-phenomenon) on the subject. However, another good entry was cre-
Creating Intransitive entries:

\[
\text{if the original subcat has a control verb (Vc \in \{\text{make, have, get, cause}\})}
\]

- \( A \ Vc \ O \Vi/Adj \)
  \[\Rightarrow S \ Vi/be Adj \quad \text{[synthetic]} \]
  \((A \ make \ O \ cry \Rightarrow S \ cry)\)

\text{else (original head is Vt)}

- \text{if Vt undergoes the S = O alternation}
  \[\Rightarrow A \ Vt \ O \quad \text{[S=0]} \]
  \((A \ turn \ O \Rightarrow S \ turn)\)

- \text{else}
  \[\Rightarrow A \ Vt \ O \Rightarrow S \ be \ Vt-ed \quad \text{[passive]} \]
  \((A \ injure \ O \ in \ X \Rightarrow S \ be \ injured \ in \ X)\)

Creating Transitive Entries: If the original subcat is:

- \( S \ Vi \)
  
  \text{if Vi undergoes the S = O alternation}
  \[\Rightarrow A \ Vt \ O \quad \text{[S=0]} \]
  \((S \ spoil \Rightarrow A \ spoil \ O)\)
  
  \text{else} \Rightarrow A \ Vc^\dagger \ O \ Vi
  \[\Rightarrow \quad \text{[synthetic]} \]
  \((S \ rot \Rightarrow A \ make \ O \ rot)\)

- \( S \ be \ Adj \Rightarrow A \ Vc^\dagger \ O \ Adj \quad \text{[synthetic]} \)
  \((S \ be \ prosperous \Rightarrow A \ make \ O \ prosperous)\)

- \( S \ be \ Vt-ed \Rightarrow A \ Vt \ O \ (by \ A) \quad \text{[passive]} \)
  \((S \ be \ defeated \ (by \ A) \Rightarrow A \ defeat \ O)\)

\[\dagger \text{We use make as the control verb, Vc}\]

Figure 4: Method of Creating English Side

The above results show that alternations can be used to create rich and useful bilingual entries. In this section we discuss some of the reasons for errors, and suggest ways to improve and expand our method.

6 Discussion and Future Work

The third source of errors was in the English translation, where the lexicographers sometimes preferred a different verb as a translation, rather than a regular alternation.

6.1 Rejecting Inappropriate Candidates

To make the construction fully automatic, a test for whether the Japanese side of the entry is appropriate or not is required.

One possibility is to add a corpus based filter: if no examples can be found that match the selectional restrictions for an entry, then it should be rejected. This could be done for each language individually. The problem with this approach is that many of the entries we created were for infrequent verbs. The average frequency in 16 years of Japanese newspaper text was only 173, and 22 verbs never appeared, although all were familiar to native speakers. We can, of course, use the web to alleviate the data sparseness problem.

6.2 Improving the English Translations

In this section we compare the distribution of the different types of translations for the reference data (§ 3.1) and the entries created by our method (§ 3.2). The breakdown is shown in Table 4. The first three rows show entries with the same English main verb.

One major discrepancy is in the frequency of the control verb construction. In Vi, no original transitive entry used control verbs. In general, when lexicographers create an entry, they prefer a simple entry to a synthetic one. Looking at the linguists’ reference data, about 6.5% of the examples used control verbs. In the constructed data, 66.1% (77 entries) use the control verb make, more than any other category. For example, when the original intransitive entry is \( N1 \ be \ exhausted \), \( exhausted \) is defined as adjective in the existing dictionary. So we create a new entry \( N1 \ make \ N2 \ exhausted \). However, there is a transitive verb exhaust, and it was preferred by the lexicographers: \( N1 \ exhaust \ N2 \). The algorithm needs to optionally convert adjectives to verbs in cases where there is overlap between the adjective and past participle.

Finally, we consider those Japanese alternations where the transitive and intransitive alternatives need translations with different English main verbs. A good example of this is \( Vi \ 亡くな

6.4 Further Work

In this paper, we targeted native Japanese verbs only. ALT-J/E already has a very high coverage of native Japanese verbs. However, even in this case, we could increase the cover of this alternation from 85% to 98% (442 out of 449 alternation pairs now in the dictionary). Most valency dictionaries or new language pairs have less cover, and so will get more results. It is also possible to use this method so as to only create half the entries by hand, and then to automatically make the alternating halves (although not all the created entries will be perfect).

In addition to the native Japanese verbs, there are many Sino-Japanese verbal nouns that undergo S=O alternation (For example, (3) ↔ (4)).

(3) 店が製品を完売した
    
mise ga seihin o kanbai-shita
    shop NOM products ACC sold out
    The shop sold out the products.

(4) 製品が完売した
    
seihin ga kanbai-shita
    products NOM sold out
    The products are sold out.

ALT-J/E’s Japanese dictionary has about 2,400 verbal nouns which have usage as both transitive and intransitive. Of these only 536 are in the valency dictionary. Our next plan is to add them all to the valency dictionary, using alternations to make the process more efficient and consistent.

Another extension is to apply the method to other alternations, using either linguists’ data or automatically acquired alternations (Oishi and Matsumoto, 1997; Furumaki and Tanaka, 2003;...
McCarthy, 2000). In particular, $S = O$ alternations make up only 34% of those discovered by Bond et al. (2002), we intend to investigate the alternations that make up the remainder.

7 Conclusion

We presented a method that uses alternation data to add new entries to an existing translation lexicon. The new entries have detailed information about argument structure and selectional restrictions. We were able to increase the coverage of the $S=O$ alternation to 98%, and the new entries gave an overall improvement in translation quality of 32%.
